MASTERARBEIT / MASTER'S THESIS

Titel der Masterarbeit / Title of the Master's Thesis

„Dietary supplements and glycaemic control in patients
with type 2 diabetes: a systematic review and
meta-analysis“

verfasst von / submitted by

Melanie Lehner, BSc

angestrebter akademischer Grad / in partial fulfilment of the requirements for the degree of
Master of Science (MSc)

Wien, 2017 / Vienna 2017

Studienkennzahl lt. Studienblatt /
degree programme code as it appears on
the student record sheet:

A 066 838

Studienrichtung lt. Studienblatt /
degree programme as it appears on
the student record sheet:

Masterstudium Ernährungswissenschaften

Betreut von / Supervisor:

Dipl. oec. troph. Dr. Georg Hoffmann, Privatdoz.

1 Acknowledgements

Firstly, I want to thank my supervisor, Dr. Georg Hoffmann, for his time, help and advice as I worked on my master's thesis. Secondly, I want to express my appreciation towards Kathi for always being there for me with an open ear not only during the process of writing my thesis, but throughout the whole duration of my master's degree. A big thanks goes out to my parents; without their love, financial and mental support the last five years of studying would not have been possible for me. I also want to thank my brother for his continued help as well as Karen and Mike for assisting me in proofreading this paper. Furthermore, I want to express my appreciation to the professors at the university of Vienna for making studying nutrition science almost always a pleasure for me. Finally, I want to thank my classmates from the university and all my friends for making the last five years one of the best times of my life that I'll always gladly look back at.

2 List of abbreviations

AA = amino acid

ABM = *Agaricus blazei* Murill

ADA = American Diabetes Association

AHA = American Heart Association

ALA = alpha-linolenic acid

BCAA = branched-chain amino acids

BMI = body mass index

CI = confidence interval

DAG = diacylglycerol

DALY = disability-adjusted life year

DHA = docosahexaenoic acid

DJC = Danzhijiangtang capsules

DPP-4 = dipeptidyl peptidase 4

EPA = eicosapentaenoic acid

EPA-E = eicosapentaenoic acid ethyl

FBG = fasting blood glucose

FPG = fasting plasma glucose

G. biloba = *Ginkgo biloba*

GLP-1 = Glucagon-like peptide 1

GLUT-4 = glucose transporter type 4

HbA1c = Glycated Haemoglobin

HDL = high-density lipoprotein

HOMA = homeostasis model assessment

IR = insulin resistance

M. charantia = *Momordica charantia*

MD = mean difference

min = minutes

MVM = multivitamin/mineral

N/A = not applicable

N. sativa = *Nigella sativa*

NIDDM = non-insulin-dependent diabetes mellitus

NNFTRI = National Nutrition and Food Technology Research Institute

OGTT = oral glucose tolerance test

OHA = oral hypoglycaemic agent

ONS = oral nutritional supplement

PA = physical activity

PPAR- δ = peroxisome proliferator activated receptor delta

RCT = randomized controlled trial

SD = standard deviation

SDI = socio-demographic index

SMD = standardized mean difference

T2DM = type 2 diabetes mellitus

TAG = triacylglycerol

UK = United Kingdom

US = United States

USA = United States of America

WHO = World Health Organization

YLD = years lived with disease/disability

YLL = years of life lost

3 List of figures

Figure 1: Global prevalence of elevated fasting blood sugar* in men aged ≥ 18 years in 2014 (age standardized estimate) [modified after (10)]	4
Figure 2: Global prevalence of elevated fasting blood sugar* in women aged ≥ 18 years in 2014 (age standardized estimate) [modified after (10)]	4

5 Introduction

5.1 Definition and description of diabetes mellitus

The group of metabolic diseases that results from failures in insulin action, insulin secretion, or both is called diabetes. The known forms of diabetes are type 1 diabetes, type 2 diabetes, gestational diabetes mellitus and other specific forms of diabetes such as genetic defects of the β -cell or insulin action, endocrinopathies caused by excess quantities of hormones that antagonize insulin action, diseases of the exocrine pancreas, infections, chemical- or drug-induced diabetes, uncommon types of immune-mediated diabetes or other genetic syndroms that are sometimes related to diabetes. One of the types of diabetes not discussed in this paper, type 1 diabetes mellitus, is caused by the destruction of the β -cells and typically results in an absolute insulin deficiency. Type 2 diabetes, formerly also known as adult-onset diabetes or non-insulin-dependent diabetes mellitus (NIDDM), is characterized by an ineffectiveness of the body to use insulin (1). This type of diabetes accounts for approximately 90-95% of people suffering from diabetes. Unlike type 1 diabetic patients, type 2 diabetics, gestational diabetics and patients with other specific forms of diabetes do not need insulin to survive but may need it for glycaemic control. (2)

The chronic hyperglycaemia that occurs in a diabetic patient leads to long-term damage of organs like the blood vessels, eyes, kidneys, nerves, and the heart. Severity of type 2 diabetes can range from a predominant insulin resistance (IR) with a relative lack of insulin to a predominant failure in insulin secretion with IR. Type 2 diabetes mellitus (T2DM) often goes years without being diagnosed due to the gradual development of hyperglycaemia and the lack of classic symptoms in early stages when the diabetes is not severe enough. Insulin concentrations may even seem normal or increased in type 2 diabetics, but their higher blood sugar levels show a β -cell malfunction in these cases. A large percentage of type 2 diabetics suffer from adiposity. Generally, elderly, obese and people lacking physical exercise are at higher risk for developing diabetes. Diabetes is also more common in women with prior gestational diabetes and people with dyslipidemia and hypertension. (2)

According to the Global Burden of Disease 2016 Causes of Death Collaborators, diabetes takes the 10th place in the ranking of the 10 leading causes of total years of life lost (YLL) in Austria, while in the United States (US) and Germany, diabetes fortunately did not make it onto the list (3). When it comes to the ranking of the leading causes for years lived with disease/disability (YLD), diabetes makes for a scary 3rd place in the US, while it takes 8th place in the German ranking and is ranked 9th in Austria – making diabetes a lesser problem in Austria compared to many other Western European countries (4). In Austria, diabetes is the 10th leading cause of all-age disability-adjusted life years (DALYs), while in Germany it is the 8th leading cause and in the US, it even accounts for the 6th leading cause of all-age DALYs (5). Looking at the development over time, diabetes has gone from 23rd place in 1990 and 16th place in 2006 to being ranked 12th in 2016 in the list of the leading level 3 causes for total DALYs (5). Meanwhile, its place in the ranking of the 30 leading level 4 causes of YLDs has barely changed – going from a 9th place in 1990 and 2006 to an 8th place in 2016 (4). While in 1990, diabetes did not even make it onto the list of the 30 leading level 3 causes for total YLLs being ranked 32nd in the low socio-demographic index (SDI) group, it ranked 23rd in 2006 and 21st in 2016 (3). In the high SDI group, diabetes has risen from rank 13 in 1990 to rank 11 in 2006 and 2016 (3). The trends for YLL and especially DALYs are evidence to just how important good diabetes therapy options have become.

There are several ways to achieve glycaemic control and improve insulin resistance; however, restoration to a normal state is rather rare (2). These measures include diet, physical activity, weight reduction, oral glucose-lowering agents and/or subcutaneous insulin injections (6). Another option that is becoming more and more common is the use of supplements to help achieve glycaemic control. Supplements are becoming more popular now that everything is accessible easily on the internet and the web also allows a fast spread of information through bloggers and other forums that praise the efficacy of these supplements. The question that arises from this movement is: Do supplements really help? This systematic review and meta-analysis aims to examine the influence of supplements on glycaemic parameters in people suffering from

diabetes mellitus type 2. Until now, a review and meta-analysis of this scale that examines every supplement that has ever been used in an randomized controlled trial (RCT) has never been done before.

5.2 Classification of diabetes

Table 1 shows the diagnostic criteria for diabetes mellitus according to the World Health Organization (WHO) as well as the American Diabetes Association (ADA). Glycated haemoglobin (HbA1c) is a widely used standard biomarker to measure chronic glycaemia, reflecting average glucose levels from the last two to three months (2).

Table 1: Diagnostic criteria for diabetes mellitus [modified after (2)]

	mg/dL	mmol/L	%	Note
Glycated Haemoglobin	N/A	N/A	≥6.5	Tests should be performed in a laboratory using methods that are National Glycohemoglobin Standardization Program certified and standardized to the Diabetes Control and Complications Trial assay.
Fasting plasma glucose	≥126	≥7.0	N/A	Fasting = no caloric intake for ≥8 hours
2-h plasma glucose in an OGTT	≥200	≥11.1	N/A	Tests should be performed according to WHO regulations (75g anhydrous sugar dissolved in water)
Random plasma glucose	≥200	≥11.1	N/A	In patients exhibiting classic symptoms of hyperglycaemia or a hyperglycaemic crisis

N/A = not applicable, WHO = World Health Organization

5.3 Prevalence of diabetes mellitus

The prevalence of diabetes in individuals aged >18 years worldwide was 8.5% in 2014 compared to 4.7% in 1980 while the total count of diabetics went from 108 million people in 1980 to 422 million people in 2014 (7). Prediction models report an estimated number of 592 million diabetics in the year 2035 (8). In 2004, the number of people suffering from diabetes mellitus was 220.5 million with the Western Pacific being ranked 1st as the region with the most diabetics with a total of 56 million people (9). However, the fastest rise of diabetes prevalence has been taking place in middle- and low-income countries (7).

Figures 1 and 2 show the global prevalence of adults with a fasting blood glucose ≥ 7.0 mmol/L or on medication for raised blood glucose in 2014 separated in male and female populations.

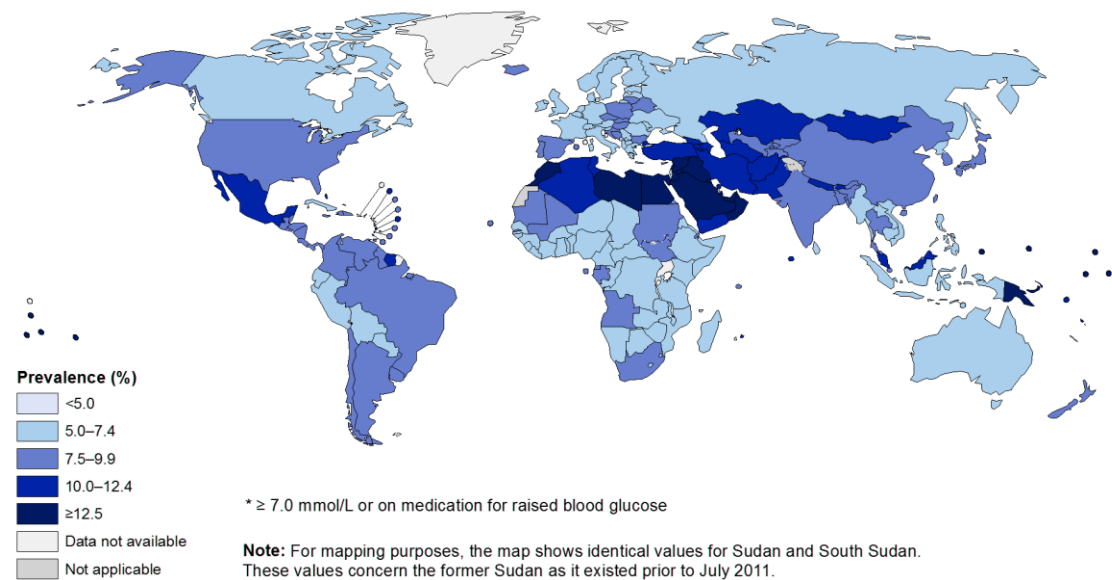

Figure 1: Global prevalence of elevated fasting blood sugar* in men aged ≥ 18 years in 2014 (age standardized estimate) [modified after (10)]

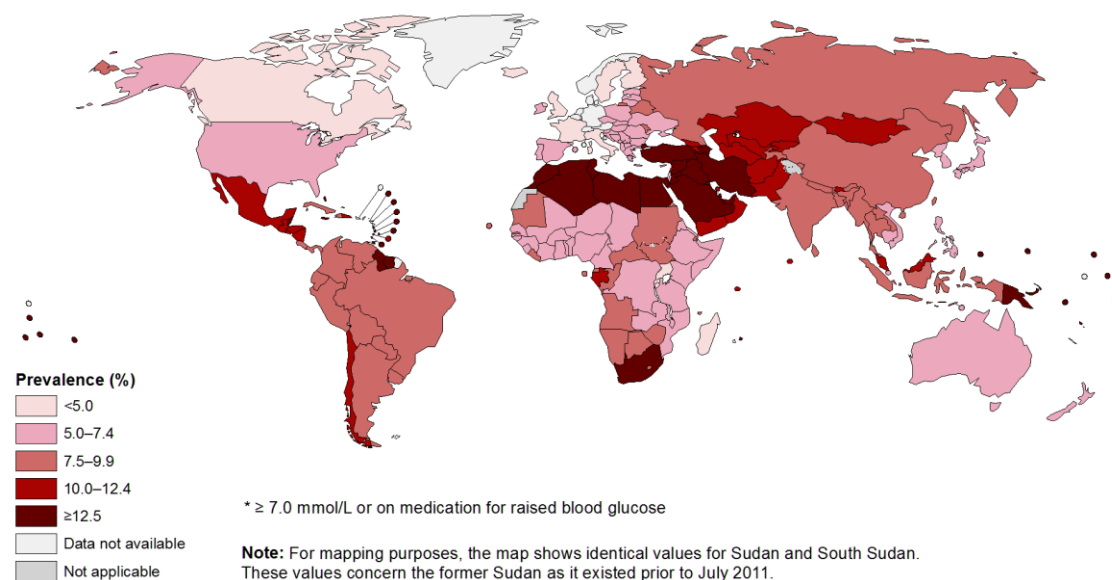

Figure 2: Global prevalence of elevated fasting blood sugar* in women aged ≥ 18 years in 2014 (age standardized estimate) [modified after (10)]

5.4 Use of supplements for glycaemic control in different countries

While non-antioxidant as well as antioxidant micronutrients are supposed to have an influence on the development and the complications of type 2 diabetes, especially micronutrients and vitamins with an antioxidant function play an important role since the complications and consequences of the disease arise from an imbalance between the formation of free radicals and their control by natural antioxidants (11, 12).

Diabetes cost the US-American healthcare system 245 billion dollars in 2012 and this sum is expected to grow as the number of diagnosed individuals increases (13). However, the efficacy of antidiabetic medication of 41% is low (14, 15) and a stable blood sugar control for more than 8 years is lacking (16). The use of metformin is associated with side effects like gastrointestinal discomfort and a potential toxicity and adverse events during sulfonylurea treatment include weight gain, hypoglycaemia and cardiovascular damage (17). Additionally, pioglitazone treatment goes along with an elevated risk of edema, bladder cancer and distal bone fractures in postmenopausal women (16). Hence, more and more patients try to manage their diabetes with alternative medicine and supplements. The use of supplements is a huge market with US-American citizens spending 12.8 billion dollars out-of-pocket on natural product supplements in 2012 (18). This is about 24% of their out-of-pocket expenditures on prescription drugs (18). Since the family income in American households has increased, out-of-pocket purchases of supplements and other complementary approaches have gone up significantly (18).

Although health claims about nutritional supplements are prohibited in Austria, Austrians spend about 100 million euros annually on supplements. Magnesium supplements appear to be the most popular. However, two thirds of these magnesium supplements contain amounts of magnesium way above the daily requirement. This can lead to vomiting, diarrhea, insomnia, irritations of the skin and could damage the liver and kidneys. In addition, the wrong combinations of supplements could interfere with their absorption. (19)

According to the 2016 forsa-survey in Germany, two thirds of the 1001 participants consumed at least one nutritional supplement in the 6-month period before the survey. The majority of consumers, as well as, about 50% of the total number of survey-participants believe in a health benefit through the use of supplements. While young adults under the age of 29 are more likely to use supplementation, level of education had no influence on the likelihood of supplement use. However, a higher level of education leads to a greater belief in the efficacy. Overall, 51% of the people believed in the efficacy of supplements while 38% of them also said that they hardly feel informed about the risks of nutritional supplementation. (20)

Surveys like these are an indication for how important it is to perform reviews and meta-analyses like this one to clarify the current situation and state of knowledge on supplements.

6 Hypothesis

H0: In RCTs, the use of supplements (vitamin C, vitamin D, vitamin E, vitamin C + E, vitamin B6, folate + vitamin B6 and 12, calcium + vitamin D, vitamin E + alpha-lipoic acid, alpha-lipoic-acid, linoleic acid, fish oil, EPA, EPA + DHA, n-3 fatty acids + low-dose aspirin, amino acids (AAs), magnesium, zinc, selenium, chromium, cinnamon, probiotics, synbiotics, prebiotics, flaxseed, zinc + flaxseed oil, garlic, coenzyme Q10, antioxidant supplements, resveratrol, Pancreas Tonic, sucralose, pistachios, yeast, the mushroom *Agaricus blazei* Murill (ABM), tea extract, silymarin, Pycnogenol, soy, cranberry extract, anthocyanin, DAG, Caiapo, diabetes-specific oral nutritional supplements (ONS), DBCare, ginger, *M. charantia*, *Nigella sativa* (*N. sativa*), whortleberry, Korean red ginseng (*Panax ginseng*) rootlets, *Ginkgo biloba* (*G. biloba*) L. leaves dry extract, berberine, Danzhijiangtang capsules (DJC, a traditional Chinese medicine), minerals + vitamins, zinc + vitamins + minerals, magnesium + zinc, melatonin + zinc) in T2DM patients has no influence on glycaemic outcomes (HbA1c, glucose, insulin, HOMA-IR [homeostasis model assessment-estimated insulin resistance], HOMA-beta, QUICKI, adiponectin, C-peptide, 2-h 75 g OGTT glucose).

H1: In RCTs, the use of supplements (vitamin C, vitamin D, vitamin E, vitamin C + E, vitamin B6, folate + vitamin B6 and 12, calcium + vitamin D, vitamin E + alpha-lipoic acid, alpha-lipoic-acid, linoleic acid, fish oil, EPA, EPA + DHA, n-3 fatty acids + low-dose aspirin, AAs, magnesium, zinc, selenium, chromium, cinnamon, probiotics, synbiotics, prebiotics, flaxseed, zinc + flaxseed oil, garlic, coenzyme Q10, antioxidant supplements, resveratrol, Pancreas Tonic, sucralose, pistachios, yeast, ABM, tea extract, silymarin, Pycnogenol, soy, cranberry extract, anthocyanin, DAG, Caiapo, diabetes-specific ONS, DBCare, ginger, *M. charantia*, *N. sativa*, whortleberry, Korean red ginseng (*Panax ginseng*) rootlets, *G. biloba* L. leaves dry extract, berberine, DJC, minerals + vitamins, zinc + vitamins + minerals, magnesium + zinc, melatonin + zinc) in T2DM patients has an influence on glycaemic outcomes (HbA1c, glucose, insulin, HOMA-IR, HOMA-beta, QUICKI, adiponectin, C-peptide, 2-h 75 g OGTT glucose).

7 Methods

7.1 Data sources and searches

The preliminary registration number of the present systematic review and meta-analysis within the PROSPERO database „International prospective register of systematic reviews“ is 76434.

A literature search was performed in the online databases PubMed (from 1966), Web of Science (from 1899) and the Cochrane Trial Register until May 2017. PubMed was searched using the search terms: (supplement*[tiab] OR vitamin*[tiab] OR multimineral*[tiab] OR cholecalciferol[tiab] OR ergocalciferol[tiab] OR ascorbic acid[tiab] OR antioxidant*[tiab] OR protein[tiab] OR amino acid*[tiab] OR micronutrient*[tiab] OR calcium[tiab] OR magnesium[tiab] OR potassium[tiab] OR selenium[tiab] OR iron[tiab] OR zinc[tiab] OR omega 3[tiab] OR fatty acid*[tiab] OR fiber[tiab] OR fibre[tiab] OR beta carotene[tiab] OR folic acid[tiab] OR niacin[tiab] OR thiamine[tiab] OR riboflavin[tiab] OR eicosapentaenoic acid[tiab] OR docosahexaenoic acid[tiab] OR linolenic acid[tiab] OR olive oil[tiab] OR inulin[tiab] OR psyllium[tiab] OR cellulose[tiab] OR copper[tiab] OR iodine[tiab] OR prebiotics[tiab] OR probiotics[tiab] OR synbiotics[tiab]) AND (diabetes[MeSH]) AND (Hemoglobin A, Glycosylated[tiab] OR insulin[tiab] OR fasting serum glucose[tiab] OR fasting plasma glucose[tiab] OR fasting glucose[tiab] OR glucose tolerance[tiab] OR hemoglobin A1c[tiab] OR glycated hemoglobin[tiab]) NOT (Case-Control Studies[MeSH] OR Cohort Studies[MeSH] OR case-control[tiab] OR cohort[tiab] OR case-report[tiab] OR adolescents[All Fields] OR children[All Fields] OR gestational[tiab] OR pregnant[tiab] OR pregnancy[tiab]) NOT (rats[tiab] OR monkeys[tiab] OR primates[tiab] OR rabbits[tiab] OR cats[tiab] OR dogs[tiab] OR mice[tiab] OR pigs[tiab] OR cows[tiab]) AND ((Randomized Controlled Trial[ptyp] OR Clinical Trial[ptyp]) AND humans[MeSH Terms] AND adult[MeSH Terms]), while Web of Science was searched using the terms: TS=(supplement*[tiab] OR vitamin*[tiab] OR multimineral*[tiab] OR cholecalciferol[tiab] OR ergocalciferol[tiab] OR ascorbic acid[tiab] OR antioxidant*[tiab] OR protein[tiab] OR amino acid*[tiab] OR micronutrient*[tiab] OR calcium[tiab] OR magnesium[tiab] OR potassium[tiab] OR selenium[tiab] OR iron[tiab] OR

zinc[tiab] OR omega 3[tiab] OR fatty acid*[tiab] OR fiber[tiab] OR fibre[tiab] OR beta carotene[tiab] OR folic acid[tiab] OR niacin[tiab] OR thiamine[tiab] OR riboflavin[tiab] OR eicosapentaenoic acid[tiab] OR docosahexaenoic acid[tiab] OR linolenic acid[tiab] OR olive oil[tiab] OR inulin OR psyllium OR cellulose OR copper[OR iodine OR prebiotics OR probiotics OR synbiotics) AND TS=(diabetes) AND TS=(Hemoglobin A, Glycosylated OR insulin OR fasting serum glucose OR fasting plasma glucose OR fasting glucose OR glucose tolerance OR hemoglobin A1c OR glycated hemoglobin) and the Cochrane Trials Register was searched using: (supplement*(tiab) OR vitamin*(tiab) OR multimineral*(tiab) OR cholecalciferol(tiab) OR ergocalciferol(tiab) OR ascorbic acid(tiab) OR antioxidant*(tiab) OR protein(tiab) OR amino acid*(tiab) OR micronutrient*(tiab) OR calcium(tiab) OR magnesium(tiab) OR potassium(tiab) OR selenium(tiab) OR iron(tiab) OR zinc(tiab) OR omega 3(tiab) OR fatty acid*(tiab) OR fiber(tiab) OR fibre(tiab) OR beta carotene(tiab) OR folic acid(tiab) OR niacin(tiab) OR thiamine(tiab) OR riboflavin(tiab) OR eicosapentaenoic acid(tiab) OR docosahexaenoic acid(tiab) OR linolenic acid(tiab) OR olive oil(tiab) OR inulin OR psyllium OR cellulose OR copper OR iodine OR prebiotics OR probiotics OR synbiotics) AND diabetes. The languages were restricted to English, German and Dutch.

Additionally, reviews and meta-analyses found through the database search were screened manually for further eligible studies. The authors were contacted for trials that could not be accessed online.

7.2 Eligibility criteria

Studies were included if they met the following criteria: 1) RCT design including crossover design; 2) humans only; 3) adults only (≥ 18 years); 4) a minimum intervention duration of 12 weeks; 5) patients with established type 2 diabetes mellitus; and 6) the assessment of glycaemic control as outcome parameter. Included in the meta-analysis was the supplementation with: vitamin C, vitamin D, vitamin E, vitamin C + E, vitamin B6, folate + vitamin B6 and 12, calcium + vitamin D, vitamin E + alpha-lipoic acid, alpha-lipoic-acid, linoleic acid, fish oil, EPA, EPA + DHA, n-3 fatty acids + low-dose aspirin, AAs, magnesium, zinc,

selenium, chromium, cinnamon, probiotics, synbiotics, prebiotics, flaxseed, zinc + flaxseed oil, garlic, coenzyme Q10, antioxidant supplements, resveratrol, Pancreas Tonic, sucralose, pistachios, yeast, ABM, tea extract, silymarin, Pycnogenol, soy, cranberry extract, anthocyanin, diacylglycerol, Caiapo, diabetes-specific ONS, DBCare, ginger, *M. charantia*, *N. sativa*, whortleberry, Korean red ginseng (*Panax ginseng*) rootlets, *G. biloba* L. leaves dry extract, berberine, DJC, minerals + vitamins, zinc + vitamins + minerals, magnesium + zinc, melatonin + zinc.

7.3 Exclusion criteria

Studies about gestational diabetes mellitus, type 1 diabetes mellitus and prediabetes were excluded.

7.4 Data extraction

First, the titles and abstracts of all retrieved records were screened. Full texts of records that passed the title and abstract screening were retrieved and examined based on the eligibility and exclusion criteria mentioned above.

7.5 Statistical analysis

The Review Manager 5.3 (Nordic Cochrane Center, Copenhagen) was used to perform the statistical analysis. Standard pairwise meta-analyses of all studies that intervened with the same supplement were performed. The pooled effects of the interventions were examined as mean differences (MD). In a random-effects model, either the post-intervention means \pm standard deviations (SD) or the changes from baseline values \pm standard deviation of intervention and control group were compared. If data was given as mean \pm standard errors or mean and 95% confidence interval (CI), the standard error was converted into SD using $SD = SE \times \sqrt{N}$. The confidence interval was converted using $SD = [(\sqrt{N}) \times (\text{upper limit} - \text{lower limit})] \div [t_{inv}(1-0.95; N-1) \times 2]$. The outcomes are depicted as forest plots. Funnel plots were used for those cases where there were at least five trials using the same supplement to examine one of the nine outcome parameters. Funnel plots are used in meta-analyses to identify possible publication bias. In a

scatterplot, the therapy effect on the x-axis is plotted against the SD on the y-axis. A symmetric form indicates a balanced trial publication. Results from bigger studies should be more precise and therefore closer to the mean formed by all study results.

8 Results

Figure 3 illustrates the process from the 2831 hits in the three databases PUBMED, Web of Science and the Cochrane Trial Register and the 13 studies handpicked from reviews and meta-analyses to the 122 trials that were included in the systematic review and the 105 trials included in the meta-analysis in form of a flow chart.

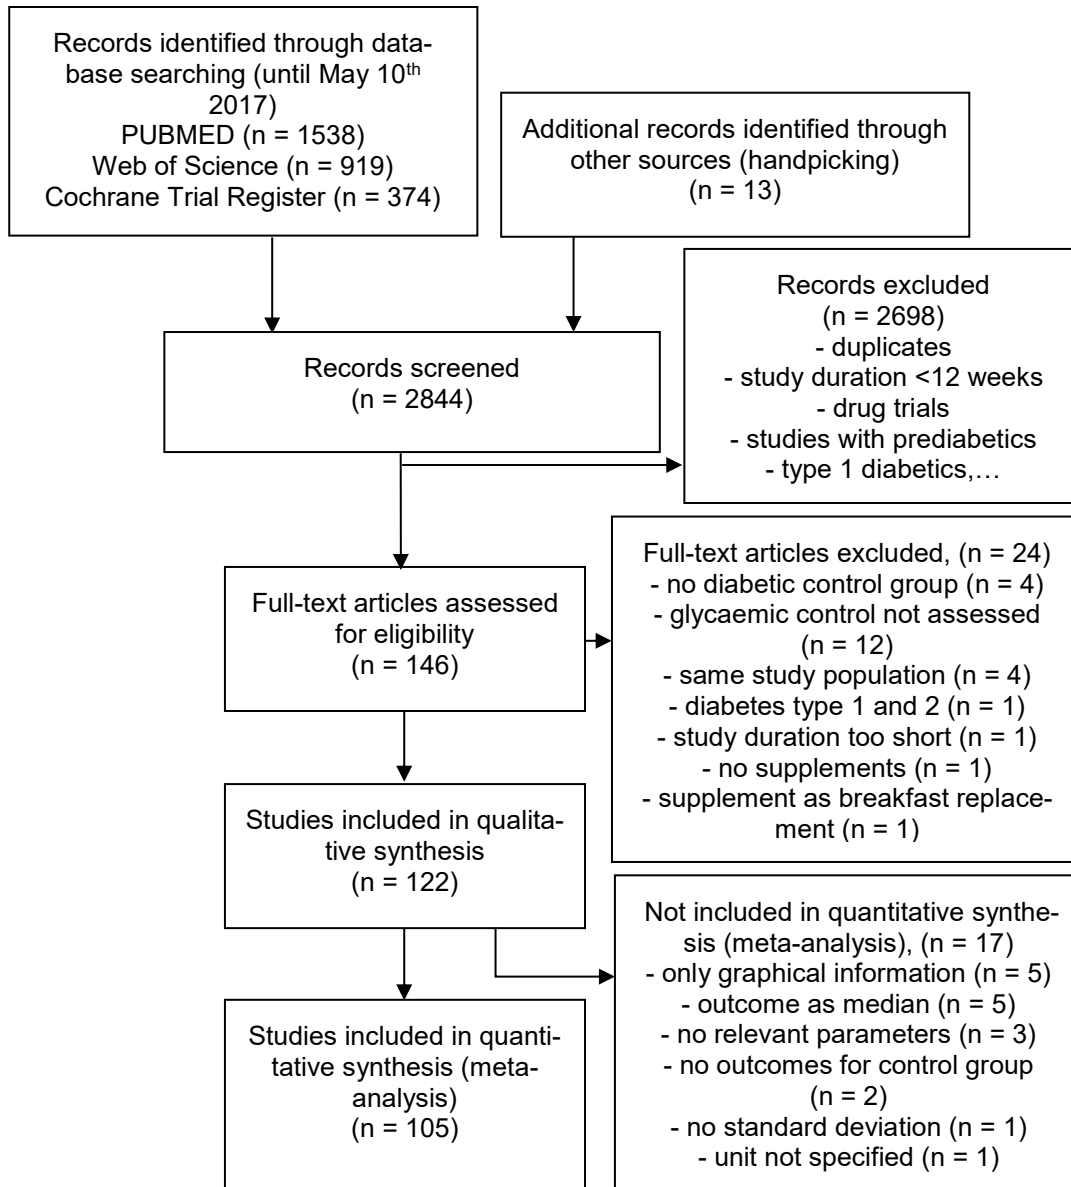

Figure 3: Flow diagram

Table 2 shows the general study characteristics of the 122 studies included in this review.

Table 3 shows the treatment arms and number of participants at randomization as well as at time of analysis in the 122 trials of the systematic review. For a clearer arrangement, this table has been separated into three parts. Five columns for four treatment arms in the beginning, a part with 16 columns and 15 treatment arms for the study by Mitra and Bhattacharya, and another part with five columns, four treatment arms for the remaining studies.

Table 3: Description of control and intervention arms and number of participants according to the different arms of the included trials

8.1 HbA1c

Figure 4 shows that the decrease in HbA1c was significantly more pronounced following prebiotic supplementation compared to their respective control groups: MD -0.38% [95% CI -0.60, -0.16], $P = 0.0006$.

Figure 4: Forest plot showing aggregated weighted MD including 95% CI for HbA1c after prebiotic supplementation vs. control.

The squares represent the point estimates of the intervention effect, the horizontal lines represent the corresponding 95% CI. The dimension of the squares indicates the weight of the study within the meta-analysis. The diamond summarizes the pooled MDs with 95% CI for all randomized trials. CI = confidence interval, HbA1c = Glycated Haemoglobin, I^2 = heterogeneity, MD = mean difference, SD = standard deviation, high = high dose of psyllium, low = low dose of psyllium

Compared to their respective control groups, decrease in HbA1c was significantly more distinct following AA supplementation: MD -0.36% [95% CI -0.67, -0.05], $P = 0.02$ (Figure 5). A sensitivity analysis showed a non-significant decrease in HbA1c after exclusion of all data on L-canitine: MD -0.34 [95% CI -0.91, 0.24], $P = 0.25$

Figure 5: Forest plot showing aggregated weighted MD including 95% CI for HbA1c after AA supplementation vs. control.

The squares represent the point estimates of the intervention effect, the horizontal lines represent the corresponding 95% CI. The dimension of the squares indicates the weight of the study within the meta-analysis. The diamond summarizes the pooled MDs with 95% CI for all randomized trials. AA = amino acid, CI = confidence interval, HbA1c = Glycated Haemoglobin, I^2 = heterogeneity, MD = mean difference, SD = standard deviation

Decrease in HbA1c was significantly more pronounced following vitamin E supplementation compared to their respective control groups: MD -0.56% [95% CI -0.83, -0.29], $P < 0.0001$ (Figure 6).

Figure 6: Forest plot showing aggregated weighted MD including 95% CI for HbA1c after vitamin E supplementation vs. control.

The squares represent the point estimates of the intervention effect, the horizontal lines represent the corresponding 95% CI. The dimension of the squares indicates the weight of the study within the meta-analysis. The diamond summarizes the pooled MDs with 95% CI for all randomized trials. CI = confidence interval, HbA1c = Glycated Haemoglobin, I^2 = heterogeneity, MD = mean difference, SD = standard deviation

Figure 7 shows that compared to their respective control groups, decrease in HbA1c was significantly more distinct following flaxseed supplementation: MD -0.54% [95% CI -0.95, -0.12], $P = 0.01$.

Figure 7: Forest plot showing aggregated weighted MD including 95% CI for HbA1c after flaxseed supplementation vs. control.

The squares represent the point estimates of the intervention effect, the horizontal lines represent the corresponding 95% CI. The dimension of the squares indicates the weight of the study within the meta-analysis. The diamond summarizes the pooled MDs with 95% CI for all randomized trials. CI = confidence interval, HbA1c = Glycated Haemoglobin, I^2 = heterogeneity, MD = mean difference, SD = standard deviation

Figure 8 shows that the decrease in HbA1c was significantly more pronounced following the supplementation of berberine compared to their respective control groups: MD -0.66% [95% CI -1.00, -0.33], $P = 0.0001$.

Figure 8: Forest plot showing aggregated weighted MD including 95% CI for HbA1c after berberine supplementation vs. control.

The squares represent the point estimates of the intervention effect, the horizontal lines represent the corresponding 95% CI. The dimension of the squares indicates the weight of the study within the meta-analysis. The diamond summarizes the pooled MDs with 95% CI for all randomized trials. CI = confidence interval, HbA1c = Glycated Haemoglobin, I^2 = heterogeneity, MD = mean difference, SD = standard deviation

Compared to their respective control groups, decrease in HbA1c was significantly more distinct following the supplementation of silymarin: MD -1.92% [95% CI -3.32, -0.51], $P = 0.007$ (Figure 9).

Figure 9: Forest plot showing aggregated weighted MD including 95% CI for HbA1c after silymarin supplementation vs. control.

The squares represent the point estimates of the intervention effect, the horizontal lines represent the corresponding 95% CI. The dimension of the squares indicates the weight of the study within the meta-analysis. The diamond summarizes the pooled MDs with 95% CI for all randomized trials. CI = confidence interval, HbA1c = Glycated Haemoglobin, I^2 = heterogeneity, MD = mean difference, SD = standard deviation

Decrease in HbA1c was significantly more pronounced following the supplementation of zinc, vitamins and minerals compared to the control group: MD -0.68% [95% CI -1.32, -0.04], $P = 0.04$ (Figure 10).

Figure 10: Forest plot showing the aggregated weighted MD including 95% CI for HbA1c after zinc, vitamin and mineral supplementation vs. control.

The square represents the point estimates of the intervention effect, the horizontal line represents the corresponding 95% CI. The dimension of the square indicates the weight of the study

within the meta-analysis. The diamond summarizes the pooled MD with 95% CI for all randomized trials. CI = confidence interval, HbA1c = Glycated Haemoglobin, I^2 = heterogeneity, MD = mean difference, SD = standard deviation

Figure 11 shows that compared to the control group, decrease in HbA1c was significantly more distinct following the supplementation of melatonin and zinc: MD -2.09% [95% CI -3.26, -0.92], $P = 0.0004$.

Figure 11: Forest plot showing the aggregated weighted MD including 95% CI for HbA1c after melatonin and zinc supplementation vs. control.

The square represents the point estimates of the intervention effect, the horizontal line represents the corresponding 95% CI. The dimension of the square indicates the weight of the study within the meta-analysis. The diamond summarizes the pooled MD with 95% CI for all randomized trials. CI = confidence interval, HbA1c = Glycated Haemoglobin, I^2 = heterogeneity, MD = mean difference, SD = standard deviation

Compared to the control group, decrease in HbA1c was significantly more distinct following calcium and vitamin D supplementation: MD -1.40% [95% CI -2.08, -0.72], $P < 0.0001$ (Figure 12).

Figure 12: Forest plot showing the aggregated weighted MD including 95% CI for HbA1c after calcium and vitamin D supplementation vs. control.

The square represents the point estimates of the intervention effect, the horizontal line represents the corresponding 95% CI. The dimension of the square indicates the weight of the study within the meta-analysis. The diamond summarizes the pooled MD with 95% CI for all randomized trials. CI = confidence interval, HbA1c = Glycated Haemoglobin, I^2 = heterogeneity, MD = mean difference, SD = standard deviation

Decrease in HbA1c was significantly more pronounced following alpha-lipoic acid supplementation compared to the control group: MD -0.50% [95% CI -0.62, -0.38], $P < 0.00001$ (Figure 13).

Figure 13: Forest plot showing the aggregated weighted MD including 95% CI for HbA1c after alpha-lipoic acid supplementation vs. control.

The square represents the point estimates of the intervention effect, the horizontal line represents the corresponding 95% CI. The dimension of the square indicates the weight of the study within the meta-analysis. The diamond summarizes the pooled MD with 95% CI for all randomized trials. CI = confidence interval, HbA1c = Glycated Haemoglobin, I^2 = heterogeneity, MD = mean difference, SD = standard deviation

Figure 14 shows that compared to the control group, decrease in HbA1c was significantly more distinct following pistachio supplementation: MD -0.40% [95% CI -0.64, -0.16], P = 0.001.

Figure 14: Forest plot showing the aggregated weighted MD including 95% CI for HbA1c after pistachio supplementation vs. control.

The square represents the point estimates of the intervention effect, the horizontal line represents the corresponding 95% CI. The dimension of the square indicates the weight of the study within the meta-analysis. The diamond summarizes the pooled MD with 95% CI for all randomized trials. CI = confidence interval, HbA1c = Glycated Haemoglobin, I^2 = heterogeneity, MD = mean difference, SD = standard deviation

Figure 15 shows that the decrease in HbA1c was significantly more pronounced following the supplementation of Pycnogenol compared to the control group: MD -0.90% [95% CI -1.78, -0.02], P = 0.04.

Figure 15: Forest plot showing the aggregated weighted MD including 95% CI for HbA1c after Pycnogenol supplementation vs. control.

The square represents the point estimates of the intervention effect, the horizontal line represents the corresponding 95% CI. The dimension of the square indicates the weight of the study within the meta-analysis. The diamond summarizes the pooled MD with 95% CI for all randomized trials. CI = confidence interval, HbA1c = Glycated Haemoglobin, I^2 = heterogeneity, MD = mean difference, SD = standard deviation

Figure 16 shows that the increase in HbA1c was significantly more pronounced following zinc supplementation compared to the control group: MD 0.60% [95% CI 0.05, 1.15], $P = 0.03$.

Figure 16: Forest plot showing the aggregated weighted MD including 95% CI for HbA1c after zinc supplementation vs. control.

The square represents the point estimates of the intervention effect, the horizontal line represents the corresponding 95% CI. The dimension of the square indicates the weight of the study within the meta-analysis. The diamond summarizes the pooled MD with 95% CI for all randomized trials. CI = confidence interval, HbA1c = Glycated Haemoglobin, I^2 = heterogeneity, MD = mean difference, SD = standard deviation

Compared to the control group, the increase in HbA1c was significantly more distinct following the supplementation of a diabetes specific ONS: MD 1.85% [95% CI 1.02, 2.68], $P < 0.0001$ (Figure 17).

Figure 17: Forest plot showing the aggregated weighted MD including 95% CI for HbA1c after a diabetes-specific ONS vs. control.

The square represents the point estimates of the intervention effect, the horizontal line represents the corresponding 95% CI. The dimension of the square indicates the weight of the study within the meta-analysis. The diamond summarizes the pooled MD with 95% CI for all randomized trials. CI = confidence interval, HbA1c = Glycated Haemoglobin, I^2 = heterogeneity, MD = mean difference, SD = standard deviation

Figure 18 shows that supplementation of ginger was close to having a significant influence on the change in HbA1c compared to the control group: MD -0.70% [95% CI -1.45, 0.05], $P = 0.07$.

Figure 18: Forest plot showing the aggregated weighted MD including 95% CI for HbA1c after ginger vs. control.

The square represents the point estimates of the intervention effect, the horizontal line represents the corresponding 95% CI. The dimension of the square indicates the weight of the study within the meta-analysis. The diamond summarizes the pooled MD with 95% CI for all randomized trials. CI = confidence interval, HbA1c = Glycated Haemoglobin, I^2 = heterogeneity, MD = mean difference, SD = standard deviation

8.2 Glucose

Figure 19 shows that the decrease in glucose was significantly more pronounced following prebiotic supplementation compared to their respective control groups: MD -0.83 mmol/L [95% CI -1.55, -0.10], P = 0.03.

Figure 19: Forest plot showing the aggregated weighted MD including 95% CI for glucose after prebiotic supplementation vs. control.

The squares represent the point estimates of the intervention effect, the horizontal lines represent the corresponding 95% CI. The dimension of the squares indicates the weight of the study within the meta-analysis. The diamond summarizes the pooled MDs with 95% CI for all randomized trials. CI = confidence interval, I^2 = heterogeneity, MD = mean difference, SD = standard deviation, high = high dose of psyllium, low = low dose of psyllium

Compared to their respective control groups, decrease in glucose was significantly more distinct following AA supplementation: MD -0.40 mmol/L [95% CI -0.48, -0.32], P < 0.00001 (Figure 20). A sensitivity analysis showed a non-significant decrease in glucose after exclusion of all data on L-canitine: MD -0.24 [95% CI -0.83, 0.34], P = 0.42

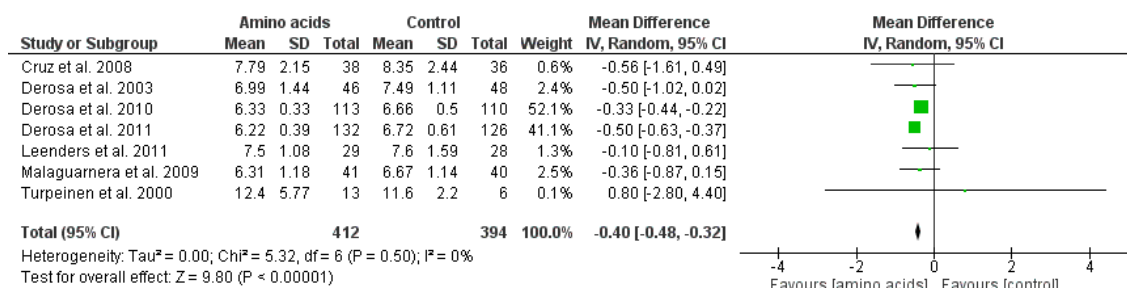

Figure 20: Forest plot showing the aggregated weighted MD including 95% CI for glucose after AA supplementation vs. control.

The squares represent the point estimates of the intervention effect, the horizontal lines represent the corresponding 95% CI. The dimension of the squares indicates the weight of the study within the meta-analysis. The diamond summarizes the pooled MDs with 95% CI for all randomized trials. AA = amino acid, CI = confidence interval, I^2 = heterogeneity, MD = mean difference, SD = standard deviation

Decrease in glucose was significantly more pronounced following vitamin C supplementation compared to their respective control groups: MD -0.65 mmol/L [95% CI -1.07, -0.23], $P = 0.003$ (Figure 21).

Figure 21: Forest plot showing the aggregated weighted MD including 95% CI for glucose after vitamin C supplementation vs. control.

The squares represent the point estimates of the intervention effect, the horizontal lines represent the corresponding 95% CI. The dimension of the squares indicates the weight of the study within the meta-analysis. The diamond summarizes the pooled MDs with 95% CI for all randomized trials. CI = confidence interval, I^2 = heterogeneity, MD = mean difference, SD = standard deviation

Figure 22 shows that compared to their respective control groups, decrease in glucose was significantly more distinct following flaxseed supplementation: MD -0.98 mmol/L [95% CI -1.18, -0.79], $P < 0.00001$.

Figure 22: Forest plot showing the aggregated weighted MD including 95% CI for glucose after flaxseed supplementation vs. control.

The squares represent the point estimates of the intervention effect, the horizontal lines represent the corresponding 95% CI. The dimension of the squares indicates the weight of the study within the meta-analysis. The diamond summarizes the pooled MDs with 95% CI for all randomized trials. CI = confidence interval, I^2 = heterogeneity, MD = mean difference, SD = standard deviation

Figure 23 shows that the decrease in glucose was significantly more pronounced following the supplementation of probiotics compared to their respective control groups: MD -0.85 mmol/L [95% CI -1.50, -0.21], $P = 0.010$.

Figure 23: Forest plot showing the aggregated weighted MD including 95% CI for glucose after probiotic supplementation vs. control.

The squares represent the point estimates of the intervention effect, the horizontal lines represent the corresponding 95% CI. The dimension of the squares indicates the weight of the study within the meta-analysis. The diamond summarizes the pooled MDs with 95% CI for all randomized trials. CI = confidence interval, I^2 = heterogeneity, MD = mean difference, SD = standard deviation, high = high dose *L. reuteri*, low = low dose *L. reuteri*

Compared to their respective control groups, decrease in glucose was significantly more distinct following the supplementation of DAG: MD -0.74 mmol/L [95% CI -1.39, -0.09], $P = 0.03$ (Figure 24).

Figure 24: Forest plot showing the aggregated weighted MD including 95% CI for glucose after DAG supplementation vs. control.

The squares represent the point estimates of the intervention effect, the horizontal lines represent the corresponding 95% CI. The dimension of the squares indicates the weight of the study within the meta-analysis. The diamond summarizes the pooled MDs with 95% CI for all randomized trials. CI = confidence interval, I^2 = heterogeneity, MD = mean difference, SD = standard deviation, normal weight = normal weight subjects, overweight = overweight subjects

Decrease in glucose was significantly more pronounced following the supplementation of berberine compared to their respective control groups: MD -0.76 mmol/L [95% CI -1.24, -0.29], $P = 0.002$ (Figure 25).

Figure 25: Forest plot showing the aggregated weighted MD including 95% CI for glucose after berberine supplementation vs. control.

The squares represent the point estimates of the intervention effect, the horizontal lines represent the corresponding 95% CI. The dimension of the squares indicates the weight of the study within the meta-analysis. The diamond summarizes the pooled MDs with 95% CI for all randomized trials. CI = confidence interval, I^2 = heterogeneity, MD = mean difference, SD = standard deviation

Figure 26 shows that compared to their respective control groups, decrease in glucose was significantly more distinct following the supplementation of silymarin: MD -2.11 mmol/L [95% CI -3.69, -0.53], $P = 0.0009$.

Figure 26: Forest plot showing the aggregated weighted MD including 95% CI for glucose after silymarin supplementation vs. control.

The squares represent the point estimates of the intervention effect, the horizontal lines represent the corresponding 95% CI. The dimension of the squares indicates the weight of the study within the meta-analysis. The diamond summarizes the pooled MDs with 95% CI for all randomized trials. CI = confidence interval, I^2 = heterogeneity, MD = mean difference, SD = standard deviation

Compared to the control group, decrease in glucose was significantly more distinct following pistachio supplementation: MD -0.89 mmol/L [95% CI -1.45, -0.33], $P = 0.002$ (Figure 27).

Figure 27: Forest plot showing the aggregated weighted MD including 95% CI for glucose after pistachio supplementation vs. control.

The square represents the point estimates of the intervention effect, the horizontal line represents the corresponding 95% CI. The dimension of the square indicates the weight of the study within the meta-analysis. The diamond summarizes the pooled MD with 95% CI for all randomized trials. CI = confidence interval, I^2 = heterogeneity, MD = mean difference, SD = standard deviation

Decrease in glucose was significantly more pronounced following Caiapo supplementation compared to the control group: MD -0.73 mmol/L [95% CI -1.43, -0.03], P = 0.04 (Figure 28).

Figure 28: Forest plot showing the aggregated weighted MD including 95% CI for glucose after Caiapo supplementation vs. control.

The square represents the point estimates of the intervention effect, the horizontal line represents the corresponding 95% CI. The dimension of the square indicates the weight of the study within the meta-analysis. The diamond summarizes the pooled MD with 95% CI for all randomized trials. CI = confidence interval, I^2 = heterogeneity, MD = mean difference, SD = standard deviation

Figure 29 shows that compared to the control group, decrease in glucose was significantly more distinct following Pycnogenol supplementation: MD -1.98 mmol/L [95% CI -3.59, -0.37], P = 0.02.

Figure 29: Forest plot showing the aggregated weighted MD including 95% CI for glucose after Pycnogenol supplementation vs. control.

The square represents the point estimates of the intervention effect, the horizontal line represents the corresponding 95% CI. The dimension of the square indicates the weight of the study

within the meta-analysis. The diamond summarizes the pooled MD with 95% CI for all randomized trials. CI = confidence interval, I^2 = heterogeneity, MD = mean difference, SD = standard deviation

Supplementation of calcium and vitamin D was close to having a significant impact on the change in glucose compared to the control group: MD -1.60 mmol/L [95% CI -3.23, 0.03], $P = 0.05$ (Figure 30).

Figure 30: Forest plot showing the aggregated weighted MD including 95% CI for glucose after calcium and vitamin D supplementation vs. control.

The square represents the point estimates of the intervention effect, the horizontal line represents the corresponding 95% CI. The dimension of the square indicates the weight of the study within the meta-analysis. The diamond summarizes the pooled MD with 95% CI for all randomized trials. CI = confidence interval, I^2 = heterogeneity, MD = mean difference, SD = standard deviation

Figure 31 shows that supplementation of linoleic acid was close to having a significant influence on the increase of glucose compared to the control group: MD 1.33 mmol/L [95% CI -0.06, 2.72], $P = 0.06$.

Figure 31: Forest plot showing the aggregated weighted MD including 95% CI for glucose after linoleic acid supplementation vs. control.

The square represents the point estimates of the intervention effect, the horizontal line represents the corresponding 95% CI. The dimension of the square indicates the weight of the study within the meta-analysis. The diamond summarizes the pooled MD with 95% CI for all randomized trials. CI = confidence interval, I^2 = heterogeneity, MD = mean difference, SD = standard deviation

8.3 Insulin

Changes in insulin levels were significantly more prominent in the intervention groups treated with vitamin C compared to the respective control groups: MD -2.66 μ U/mL [95% CI -4.51, -0.82], $P = 0.005$ (Figure 32).

Figure 32: Forest plot showing the aggregated weighted MD including 95% CI for insulin after vitamin C supplementation vs. control.

The squares represent the point estimates of the intervention effect, the horizontal lines represent the corresponding 95% CI. The dimension of the squares indicates the weight of the study within the meta-analysis. The diamond summarizes the pooled MDs with 95% CI for all randomized trials. CI = confidence interval, I² = heterogeneity, MD = mean difference, SD = standard deviation

The change in insulin level was significantly stronger in the intervention group treated with probiotics compared to the control group: MD -3.40 μ U/mL [95% CI -5.86, -0.94], P = 0.007 (Figure 33).

Figure 33: Forest plot showing the aggregated weighted MD including 95% CI for insulin after probiotic supplementation vs. control.

The square represents the point estimates of the intervention effect, the horizontal line represents the corresponding 95% CI. The dimension of the square indicates the weight of the study within the meta-analysis. The diamond summarizes the pooled MD with 95% CI for all randomized trials. CI = confidence interval, I² = heterogeneity, MD = mean difference, SD = standard deviation

The change in insulin level was significantly more prominent in the intervention group treated with calcium and vitamin D compared to the control group: MD -4.40 μ U/mL [95% CI -6.66, -2.14], P = 0.0001 (Figure 34).

Figure 34: Forest plot showing the aggregated weighted MD including 95% CI for insulin after calcium and vitamin D supplementation vs. control.

The square represents the point estimates of the intervention effect, the horizontal line represents the corresponding 95% CI. The dimension of the square indicates the weight of the study

within the meta-analysis. The diamond summarizes the pooled MD with 95% CI for all randomized trials. CI = confidence interval, I^2 = heterogeneity, MD = mean difference, SD = standard deviation

The change in insulin level was significantly stronger in the intervention group treated with ginger compared to the control group: MD -2.01 μ U/mL [95% CI -3.90, -0.12], P = 0.04 (Figure 35).

Figure 35: Forest plot showing the aggregated weighted MD including 95% CI for insulin after ginger supplementation vs. control.

The square represents the point estimates of the intervention effect, the horizontal line represents the corresponding 95% CI. The dimension of the square indicates the weight of the study within the meta-analysis. The diamond summarizes the pooled MD with 95% CI for all randomized trials. CI = confidence interval, I^2 = heterogeneity, MD = mean difference, SD = standard deviation

The change in insulin level was significantly more prominent in the intervention group treated with ABM compared to the control group: MD -5.70 UI/L [95% CI -8.97, -2.43], P = 0.0006 (Figure 36).

Figure 36: Forest plot showing the aggregated weighted MD including 95% CI for insulin after ABM supplementation vs. control.

The square represents the point estimates of the intervention effect, the horizontal line represents the corresponding 95% CI. The dimension of the square indicates the weight of the study within the meta-analysis. The diamond summarizes the pooled MD with 95% CI for all randomized trials. ABM = *Agaricus blazei* Murill, CI = confidence interval, I^2 = heterogeneity, MD = mean difference, SD = standard deviation

Figure 37 shows that the change in insulin level was significantly stronger in the intervention group treated with the DJC compared to the control group: MD -1.10 μ U/mL [95% CI -2.01, -0.19], P = 0.02.

Figure 37: Forest plot showing the aggregated weighted MD including 95% CI for insulin after DJC supplementation vs. control.

The square represents the point estimates of the intervention effect, the horizontal line represents the corresponding 95% CI. The dimension of the square indicates the weight of the study within the meta-analysis. The diamond summarizes the pooled MD with 95% CI for all randomized trials. CI = confidence interval, I^2 = heterogeneity, MD = mean difference, SD = standard deviation

The increase in insulin level was significantly stronger in the intervention groups treated with zinc, vitamins and minerals compared to the control group: MD 8.96 $\mu\text{mol/L}$ [95% CI 0.99, 16.93], P = 0.03 (Figure 38).

Figure 38: Forest plot showing the aggregated weighted MD including 95% CI for insulin after zinc, vitamin and mineral supplementation vs. control.

The square represents the point estimates of the intervention effect, the horizontal line represents the corresponding 95% CI. The dimension of the square indicates the weight of the study within the meta-analysis. The diamond summarizes the pooled MD with 95% CI for all randomized trials. CI = confidence interval, I^2 = heterogeneity, MD = mean difference, SD = standard deviation

Supplementation of vitamin D was close to having a significant influence on the changes in insulin levels compared to their respective control groups: MD -3.65 $\mu\text{U/mL}$ [95% CI -7.49, 0.20], P = 0.06 (Figure 39).

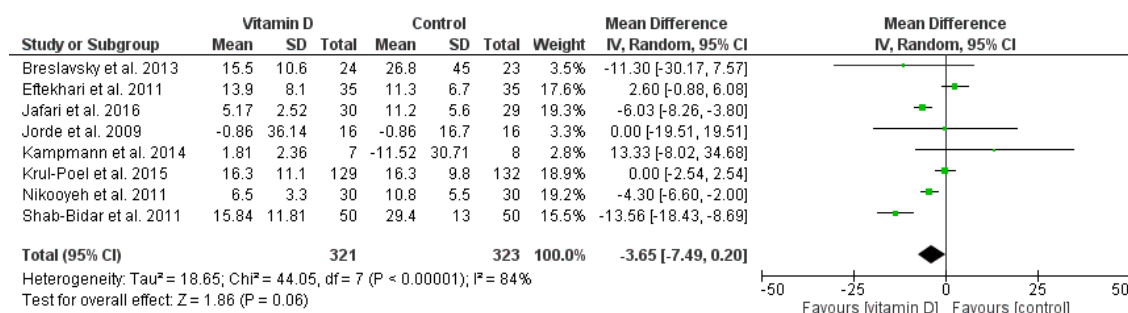

Figure 39: Forest plot showing the aggregated weighted MD including 95% CI for insulin after vitamin D supplementation vs. control.

The squares represent the point estimates of the intervention effect, the horizontal lines represent the corresponding 95% CI. The dimension of the squares indicates the weight of the study within the meta-analysis. The diamond summarizes the pooled MDs with 95% CI for all randomized trials. CI = confidence interval, I^2 = heterogeneity, MD = mean difference, SD = standard deviation

Figure 40 shows that supplementation of synbiotics was close to having a significant impact on the changes in insulin levels compared to their respective control groups: MD -4.30 μ U/mL [95% CI -8.94, 0.34], $P = 0.07$.

Figure 40: Forest plot showing the aggregated weighted MD including 95% CI for insulin after synbiotic supplementation vs. control.

The squares represent the point estimates of the intervention effect, the horizontal lines represent the corresponding 95% CI. The dimension of the squares indicates the weight of the study within the meta-analysis. The diamond summarizes the pooled MDs with 95% CI for all randomized trials. CI = confidence interval, I^2 = heterogeneity, MD = mean difference, SD = standard deviation

Supplementation of DAG was close to having a significant impact on the changes in insulin levels compared to their respective control groups: MD -6.43 μ U/mL [95% CI -13.51, 0.64], $P = 0.07$ (Figure 41).

Figure 41: Forest plot showing the aggregated weighted MD including 95% CI for insulin after DAG supplementation vs. control.

The squares represent the point estimates of the intervention effect, the horizontal lines represent the corresponding 95% CI. The dimension of the squares indicates the weight of the study within the meta-analysis. The diamond summarizes the pooled MDs with 95% CI for all randomized trials. CI = confidence interval, I^2 = heterogeneity, MD = mean difference, SD = standard deviation, normal weight = normal weight subjects, overweight = overweight subjects

8.4 HOMA-IR

Changes in HOMA-IR were significantly more prominent in the intervention groups treated with AAs compared to the respective control groups: MD -0.65 [95% CI -1.11, -0.20], $P = 0.005$ (Figure 42). A sensitivity analysis showed a non-significant change in HOMA-IR after exclusion of all data on L-carnitine: MD -0.40 [95% CI -1.44, 0.64], $P = 0.45$

Figure 42: Forest plot showing the aggregated weighted MD including 95% CI for HOMA-IR after AA supplementation vs. control.

The squares represent the point estimates of the intervention effect, the horizontal lines represent the corresponding 95% CI. The dimension of the squares indicates the weight of the study within the meta-analysis. The diamond summarizes the pooled MDs with 95% CI for all randomized trials. AA = amino acid, CI = confidence interval, I^2 = heterogeneity, MD = mean difference, SD = standard deviation

The changes in HOMA-IR were significantly stronger in the intervention groups treated with vitamin E compared to the respective control groups: MD -0.55 [95% CI -0.65, -0.45], $P < 0.00001$ (Figure 43).

Figure 43: Forest plot showing the aggregated weighted MD including 95% CI for HOMA-IR after vitamin E supplementation vs. control.

The squares represent the point estimates of the intervention effect, the horizontal lines represent the corresponding 95% CI. The dimension of the squares indicates the weight of the study within the meta-analysis. The diamond summarizes the pooled MDs with 95% CI for all randomized trials. CI = confidence interval, I^2 = heterogeneity, MD = mean difference, SD = standard deviation

The change in HOMA-IR was significantly more prominent in the intervention group treated with probiotics compared to the control group: MD -2.00 [95% CI -2.90, -1.10], $P < 0.0001$ (Figure 44).

Figure 44: Forest plot showing the aggregated weighted MD including 95% CI for HOMA-IR after probiotic supplementation vs. control.

The dimension of the square indicates the weight of the study within the meta-analysis. The diamond summarizes the pooled MD with 95% CI for all randomized trials. CI = confidence interval, I^2 = heterogeneity, MD = mean difference, SD = standard deviation

The change in HOMA-IR was significantly stronger in the intervention group treated with calcium and vitamin D compared to the control group: MD -2.50 [95% CI -3.93, -1.07], P = 0.0006 (Figure 45).

Figure 45: Forest plot showing the aggregated weighted MD including 95% CI for HOMA-IR after calcium and vitamin D supplementation vs. control.

The square represents the point estimates of the intervention effect, the horizontal line represents the corresponding 95% CI. The dimension of the square indicates the weight of the study within the meta-analysis. The diamond summarizes the pooled MD with 95% CI for all randomized trials. CI = confidence interval, I^2 = heterogeneity, MD = mean difference, SD = standard deviation

The change in HOMA-IR was significantly more prominent in the intervention group treated with magnesium compared to the control group: MD -1.20 [95% CI -1.80, -0.60], P < 0.0001 (Figure 46).

Figure 46: Forest plot showing the aggregated weighted MD including 95% CI for HOMA-IR after magnesium supplementation vs. control.

The square represents the point estimates of the intervention effect, the horizontal line represents the corresponding 95% CI. The dimension of the square indicates the weight of the study

within the meta-analysis. The diamond summarizes the pooled MD with 95% CI for all randomized trials. CI = confidence interval, I^2 = heterogeneity, MD = mean difference, SD = standard deviation

The change in HOMA-IR was significantly stronger in the intervention group treated with EPA compared to the control group: MD -1.00 [95% CI -1.88, -0.12], $P = 0.03$ (Figure 47).

Figure 47: Forest plot showing the aggregated weighted MD including 95% CI for HOMA-IR after EPA supplementation vs. control.

The square represents the point estimates of the intervention effect, the horizontal line represents the corresponding 95% CI. The dimension of the square indicates the weight of the study within the meta-analysis. The diamond summarizes the pooled MD with 95% CI for all randomized trials. CI = confidence interval, I^2 = heterogeneity, MD = mean difference, SD = standard deviation

The change in HOMA-IR was significantly more prominent in the intervention group treated with ABM compared to the control group: MD -3.00 [95% CI -5.76, -0.24], $P = 0.03$ (Figure 48).

Figure 48: Forest plot showing the aggregated weighted MD including 95% CI for HOMA-IR after ABM supplementation vs. control.

The dimension of the square indicates the weight of the study within the meta-analysis. The diamond summarizes the pooled MD with 95% CI for all randomized trials. CI = confidence interval, I^2 = heterogeneity, MD = mean difference, SD = standard deviation

8.5 HOMA-beta

The change in HOMA-beta was significantly more prominent in the intervention group treated with synbiotics compared to the control group: MD -24.00 [95% CI -43.28, -4.72], P = 0.01 (Figure 51).

Figure 51: Forest plot showing the aggregated weighted MD including 95% CI for HOMA-beta after synbiotic supplementation vs. control.

The square represents the point estimates of the intervention effect, the horizontal line represents the corresponding 95% CI. The dimension of the square indicates the weight of the study

within the meta-analysis. The diamond summarizes the pooled MD with 95% CI for all randomized trials. CI = confidence interval, I^2 = heterogeneity, MD = mean difference, SD = standard deviation

8.6 QUICKI

Figure 52 shows that the increase in QUICKI was significantly more pronounced following yeast supplementation compared to the control group: MD 0.02 [95% CI 0.01, 0.03], $P = 0.0010$.

Figure 52: Forest plot showing the aggregated weighted MD including 95% CI for QUICKI after yeast supplementation vs. control.

The square represents the point estimates of the intervention effect, the horizontal line represents the corresponding 95% CI. The dimension of the square indicates the weight of the study within the meta-analysis. The diamond summarizes the pooled MD with 95% CI for all randomized trials. CI = confidence interval, I^2 = heterogeneity, MD = mean difference, SD = standard deviation

Supplementation of probiotics was close to having a significant influence on the change in QUICKI compared to the control group: MD 0.02 [95% CI 0.00, 0.04], $P = 0.01$ (Figure 53).

Figure 53: Forest plot showing the aggregated weighted MD including 95% CI for QUICKI after probiotic supplementation vs. control.

The square represents the point estimates of the intervention effect, the horizontal line represents the corresponding 95% CI. The dimension of the square indicates the weight of the study within the meta-analysis. The diamond summarizes the pooled MD with 95% CI for all randomized trials. CI = confidence interval, I^2 = heterogeneity, MD = mean difference, SD = standard deviation

8.7 Adiponectin

Figure 54 shows that the decrease in adiponectin was significantly more pronounced following AA supplementation compared to the control group: MD -1.00 µg/mL [95% CI -1.46, -0.54], $P < 0.0001$.

Figure 54: Forest plot showing the aggregated weighted MD including 95% CI for adiponectin after AA supplementation vs. control.

The square represents the point estimates of the intervention effect, the horizontal line represents the corresponding 95% CI. The dimension of the square indicates the weight of the study within the meta-analysis. The diamond summarizes the pooled MD with 95% CI for all randomized trials. AA = amino acid, CI = confidence interval, I^2 = heterogeneity, MD = mean difference, SD = standard deviation

Compared to the control group, decrease in adiponectin was significantly more distinct following Caiapo supplementation: MD -3.10 µg/mL [95% CI -4.99, -1.21], $P = 0.001$ (Figure 55).

Figure 55: Forest plot showing the aggregated weighted MD including 95% CI for adiponectin after Caiapo supplementation vs. control.

The dimension of the square indicates the weight of the study within the meta-analysis. The diamond summarizes the pooled MD with 95% CI for all randomized trials. CI = confidence interval, I^2 = heterogeneity, MD = mean difference, SD = standard deviation

8.8 C-Peptide

Increase in C-Peptide was significantly more pronounced following melatonin and zinc supplementation compared to the control group: MD 0.38 ng/mL [95% CI 0.04, 0.72], $P = 0.03$ (Figure 56).

Figure 56: Forest plot showing the aggregated weighted MD including 95% CI for C-Pep-tide after melatonin and zinc supplementation vs. control.

The square represents the point estimates of the intervention effect, the horizontal line represents the corresponding 95% CI. The dimension of the square indicates the weight of the study within the meta-analysis. The diamond summarizes the pooled MD with 95% CI for all randomized trials. CI = confidence interval, I^2 = heterogeneity, MD = mean difference, SD = standard deviation

8.9 2-h 75 g OGTT glucose

Decrease in 2-h 75 g OGTT glucose was significantly more pronounced following berberine supplementation compared to the control group: MD -2.10 mmol/L [95% CI -3.15, -1.05], $P < 0.0001$ (Figure 57).

Figure 57: Forest plot showing the aggregated weighted MD including 95% CI for 2-h 75 g OGTT glucose after berberine supplementation vs. control.

The square represents the point estimates of the intervention effect, the horizontal line represents the corresponding 95% CI. The dimension of the square indicates the weight of the study within the meta-analysis. The diamond summarizes the pooled MD with 95% CI for all randomized trials. CI = confidence interval, I^2 = heterogeneity, MD = mean difference, OGTT = OGTT = oral glucose tolerance test, SD = standard deviation

8.10 Heterogeneity

50% was used as a threshold for heterogeneity in this meta-analysis. Hence, while heterogeneity was not important for the use of vitamin E (11%) or berberine (0%) to lower HbA1c, amino acids (0%), vitamin C (0%), flaxseed (0%), probiotics (0%), DAG (0%) or berberine (0%) to reduce glucose, vitamin C (0%) or DAG (0%) to change insulin levels and amino acids (0%) or vitamin E (0%) to change HOMA-IR, heterogeneity was found for the use of prebiotics (60%), flaxseed (63%), amino acids (92%) or silymarin (86%) to decrease HbA1c, the use of prebiotics (78%), amino acids (60%) or silymarin (81%) to reduce glucose and the use of vitamin D (84%) to change insulin levels.

8.11 Publication bias

Merely the funnel plot for vitamin E supplementation and glucose levels shows only low to middle asymmetry (Figure 66), suggesting a low to moderate likelihood of a publication bias. For all other funnel plots (Figure 58-65, 67-70), high asymmetry can be seen, indicating a higher likelihood of a publication bias. Hence, a publication bias as an influencing factor in this meta-analysis can not be ruled out completely.

8.11.1 HbA1c

SE = standard error, MD = mean difference, CI = confidence interval

9 Discussion

9.1 Summary of results and possible mechanisms of action

The goal of this systematic review and meta-analysis was to examine the effect of every supplement that has been used in RCTs with type 2 diabetics so far. A total of 26 different supplements and combinations of supplements out of the 56 different supplements and combinations used lead to significant decreases or increases in the outcome parameters. Table 5 summarizes how the supplements that produced significant forest plots impacted the different outcomes. The data is presented as mean differences. The numbers in the parantheses indicate how many different studies were involved in the formation of the result.

Table 5: Summary of statistically significant results

Supplement	HbA1c (%)	Glucose (mmol/L)	Insulin (μU/mL)	HOMA-IR	HOMA-beta	QUICKI	Adiponectin (μg/mL)	C-Peptide (ng/mL)	2-h 75g OGTT glucose (mmol/L)
AAs	-0.36 (7)	-0.40 (7)		-0.65 (4)			-1.00 (1)

AAs = amino acids, DAG = diacylglycerol, DJC = Danzhijiangtang capsules, EPA = eicosapentaenoic acid, HbA1c = Glycated Haemoglobin, OGTT = oral glucose tolerance test
* unit: $\mu\text{mol/L}$, ** unit: UI/L

While the supplementation with melatonin and zinc has shown a very considerable positive effect on HbA1c (-2.09%) – especially for diabetics with HbA1c levels close to the diagnostic limit for diabetes –, this is merely the finding of a single study. Hence, this effect should further be investigated. The same applies for the effect of the Pycnogenol pill on glucose levels (-1.98 mmol/L), that of the mushroom ABM on insulin levels (-5.70UI/L) and the effect of the seeds of the *Nigella sativa* plant on HOMA-IR (-22.50). However, the positive impacts of flaxseed (-0.98 mmol/L), prebiotics (-0.83 mmol/L) and vitamin C (-0.65 mmol/L) on glucose levels and amino acids on HOMA-IR (-0.65) are fairly big and are the results of the analyses of several studies (between three and nine trials). The positive effects from most supplements that have been used to change HbA1c levels in several trials are only small (between -0.36 and -0.56%) and might not have a big enough impact to improve a type 2 diabetic's condition. Further trials investigating the effect of zinc should be conducted since the combination of zinc, vitamins and minerals or melatonin and zinc had negative effects on insulin and C-Peptide levels in the studies included in this meta-analysis.

The effect of silymarin on HbA1c (-1.92%) and blood sugar (-2.11 mmol/L) found in this meta-analysis goes along with the findings of significant decreases in HbA1c (-1.07) and FBG (-26.86 mg/dL) reported in a meta-analysis by Voroneanu et al (144). This paper's findings on vitamin C and blood glucose (-0.65 mmol/L) also agree with those found in a meta-analysis by Tabatabaei-Malazy et al (standardized mean difference [SMD]: -20.59%) (145). While this meta-analysis coincides with several meta-analyses when it comes to the statistically significant influence of probiotics on FBG [-15.92 mg/dL (146), -0.52 mmol/L (147), MD: -0.98 mmol/L (148) and SMD: -0.61 mmol/L (149)], insulin [SMD: -0.38 (150)] and HOMA-IR [SMD: -2.10 (151) and SMD: -0.99 (150)], the results also differ with some meta-analyses when it comes to glucose (150), insulin (151) and HOMA-IR (147, 149) – these other meta-analyses were unable to report significant changes in these parameters.

Below, the main supplements that occurred in several of the 105 trials included in this meta-analysis and produced forest plots with significant or almost significant results and how they are thought to positively influence the prevalence and development of type 2 diabetes mellitus will be discussed briefly.

9.1.1 Vitamin D

Associations between the risk of diabetes mellitus type 2 and a low vitamin D status have been found in cohort studies (152-157). Further studies reported relationships between β -cell dysfunction, insulin resistance and serum vitamin D levels (12). Vitamin D is important because of its vitamin D receptors in pancreatic β -cells (12). This vitamin is able to improve the insulin sensitivity through the stimulation of insulin receptor expression and the activation of peroxisome proliferator activated receptor delta (PPAR- δ) (158-161). Additionally, the expression of calbindin-D28K (vitamin D dependent on the combination of proteins and calcium) has a positive influence on the β -cells from cytokine mediated cell death and therefore diminishes the risk of type 2 diabetes (162). Vitamin D also seems to modulate the effects of cytokines and nuclear transcription factors like NF- κ B and therefore promotes pancreatic β -cell survival and improves insulin sensitivity (163).

9.1.2 Vitamin E

The risk of diabetes may be reduced through vitamin E most likely because of its antioxidant function (164, 165). It has been reported that the levels of vitamin C and vitamin E along with the concentration of other antioxidants are lower in diabetics when compared to healthy controls (166).

9.1.3 Vitamin C

Hyperglycaemia causes oxidative stress which results in a higher requirement of vitamin C in type 2 diabetics (167). Oxidative stress, HbA1c and fasting as well as postprandial blood sugar have been inversely correlated with plasma vitamin C levels (168, 169).

9.1.4 Zinc

As a cofactor for more than 300 enzymes including superoxide dismutase, the mineral zinc plays an important role in the antioxidant defense in type 2 diabetics (170). It also facilitates the neutralization and lowers the amount of free radicals in the body (171, 172). People suffering from type 2 diabetes undergo changes in zinc metabolism as well as superoxide dismutase activity, which may make zinc supplementation during the disease important to ensure a proper antioxidant defense (170).

9.1.5 Amino acids like L-carnitine or branched-chain amino acids

In contrast to the amino acids leucine and glycine that were examined in this meta-analysis as well, L-carnitine proved to be capable of significantly improving the glycaemic parameters HbA1c, blood glucose, HOMA-IR and adiponectin.

A positive effect of L-carnitine on blood sugar levels was also found in a meta-analysis by Vidal-Casariago et al (173). However, this study group was unable to find a significant change in HbA1c (173). The non-protein amino acid L-carnitine is found in food as well as it is synthesized endogenously and acts as a cofactor for the β -oxidation, facilitating the entrance of long chain fatty acid (FA) into the mitochondria as acylcarnitine esters (173). A reduction of this transport into the mitochondria results in an accumulation of triglycerides in the cytosol (173). This accumulation is connected to the pathogenesis of insulin resistance (173). Possible reasons as to why fatty acid dysregulation leads to insulin resistance could be the inhibition of glucose transporter type 4 (GLUT-4) translocation by long chain acyl-CoA, failures in insulin signalling caused by the aggregation of diacylglycerol (DAG) and acyl-CoA or mitochondrial stress and insulin resistance caused by accumulating non-metabolised fatty acids in the mitochondria (174).

Although this could not be demonstrated in this meta-analysis, branched-chain amino acids (BCAA) are also suggested to have a positive influence on the regulation of the glucose homeostasis (175, 176) and metabolic parameters like body composition, glycaemia levels and satiety (177). They have control over the release of hormones like leptin, ghrelin or glucagon-like peptide 1 (GLP-1) in fat deposits as well as in the gastrointestinal tract (177). These hormones are able

to influence the glycaemia levels and modulate the intake of food (178-183). Together with insulin, they change growth of energy-consuming tissues like the skeletal muscle or the adipose tissue by acting as anabolic signals (177). The BCAA leucine has an insulintropic function (184, 185). It helps maintaining blood sugar homeostasis by improving sugar disposal, increases the availability of amino acids for the synthesis of muscle protein and at the same time inhibits the breakdown of muscle protein (186).

9.1.6 Probiotics

Cani et al. were one of the first to demonstrate the direct role of gut microbiota in IR by showing that a high-fat diet increases certain gut bacteria that produce higher concentrations of lipopolysaccharide and trigger the progression of IR (187). Additional studies report about various bacterial metabolites that contribute to the blood sugar homeostasis (188). Compared to healthy individuals, type 2 diabetics show a significantly smaller amount of bacteria that produce butyrate (189, 190), a short chain fatty acid (SCFA) that constitutes a main energy source for the intestinal cells (191). Through mechanisms like the regulation of glucagon-like peptide 1 by binding to G protein-coupled receptors, SCFAs are able to enhance the secretion of insulin and hence, reduce the concentration of sugar in the blood (192). Short chain fatty acids also interact with histone deacetylases (151). These influence, among others, the expression of genes that are connected to the metabolism (193). Additionally, short chain fatty acids may also help keeping up the intestinal integrity and therefore directly inhibit the low-grade inflammatory response, a state closely related to T2DM (151). Clinical trials that infused feces from skinny subjects into insulin-resistant men with metabolic syndrome reported a greater amount of butyrate-producing bacteria and beneficial metabolic effects after the infusion (194).

9.1.7 Prebiotics

Prebiotic supplementation or prebiotic enriched diet may improve blood sugar homeostasis since there is a considerable interaction between dietary components like prebiotics and the gut bacteria (195). The microbiota is supposed to contribute to a low-grade inflammation that leads from a normal glucose tolerance to prediabetes and type 2 diabetes (187, 196-200).

9.1.8 Flaxseed

In flaxseed, the main n-3 fatty acid accounting for 55% of the total fatty acid content is alpha-linolenic acid (ALA), C18:3n-3, and the main lignan is secoisolariciresinol diglucoside (201). When investigating the influence of n-3 fatty acids on type 2 diabetic patients, fish oil containing eicosapentaenoic acid (EPA), C20:5n-3, and docosahexanoic acid (DHA), C22:6n-3 is usually used (202-205). Hence, it is important to evaluate the effects of ALA versus EPA and DHA (128). Secoisolariciresinol diglucoside is proposed to help prevent and delay the progression of diabetes due to its function as a precursor to antioxidant lignans *in vivo* (206-208).

9.1.9 Berberine

As a plant quaternary ammonium salt from the group of isoquinoline alkaloids, berberine can be extracted from many different plants (209). Berberine modulates PPAR protein expression and therefore regulates the lipid and sugar metabolism in the liver. A review by Pang et al has shown that berberine may be capable of enhancing the glucolipid metabolism (209). It also accumulates beneficial gut bacteria and inhibits harmful bacteria (210-213). Additionally, it could ameliorate insulin secretion and sensitivity and decrease the intestinal glucose absorption on top of its antioxidant activities that could tackle diabetic complications. (214-223)

9.1.10 Silymarin

Silymarin is the extract of milk thistle, *Silybum marianum*, an edible plant, and acts as an antioxidant (144). In a mice model, silymarin attenuates the continuous increase of plasma sugar induced by alloxan (224).

9.1.11 Diacylglycerol

Diacylglycerol naturally occurs in different edible oils like soybean, corn, safflower or olive oil (225). In previous studies with diabetics, diacylglycerol lowered HbA1c when combined with diet treatment (226) and diminished the fasting as well as the postprandial serum triacylglycerol levels (227, 228). Trials carried out with animals reported lower levels of serum leptin and insulin through the consumption of diacylglycerol (229).

9.1.12 Other rare supplements used for glycaemic control

Other supplements included in this meta-analysis, that sometimes even lead to statistically significant changes in glycaemic parameters but might not be well-known, are Pancreas Tonic, an Ayurvedic botanical mixture available in North America under the trades names AntiBetic or Pancreas Tonic (64); Pycnogenol, an extract from *Pinus maritima*, a French maritime pine, that exhibits considerable antioxidant functions and primarily consists of flavonoids and phenolic compounds such as taxifolin, catechin or epicatechin (230); Caiapo, an extract of the skin of a potato called *Ipomea batatas* grown in Japan's Kagawa region (85); DBCare, a traditional nutritional supplement sold in India that comprises 11 herbs and is obtainable electronically worldwide (114); *Momordica charantia* (*M. charantia*), a plant also called Ampalaya with charantin, vicine and polypeptide *p* as its active ingredients – the later being structurally animal insulin alike (36); *Nigella sativa* seeds, an annual Ranunculaceae herbaceous plant with antioxidant properties (73); and the dry extract of *Ginkgo biloba* L. leaves, a natural antioxidant containing 20-27% flavonoids like quercetin, kaempferol, isorhamnetin or proanthocyanidins, 5-10% organic acids and 5-7% terpenoids (231, 232).

9.2 Limitations

This systematic review and meta-analysis is characterized by strenghts as well as limitations. First of all, it does not include unpublished data. The funnel plots show that the existance of a publication bias when it comes to the use of supplements to treat type 2 diabetes mellitus patients is very probable. The lack

of negative study results could be the result of journals being more likely to publish positive results as well as the conflict of interest that arises from the sources most supplement trials are funded with. The considerable heterogeneity found for some of the parameters may originate from the very heterogenic designs of the trials. Some studies worked solely with men, some only with women, some with both genders; the study duration ranked anywhere from 3 months all the way to 18 months; the treatment for the control groups also varied – some got a placebo, some got no treatment at all which didn't allow for an allocation concealment. Some trials did not really have a control group at all but instead compared two different supplement treatments like fish and flaxseed oil (94) or amino acids and magnesium (46). By doing so, these study groups basically implied the assumption that one treatment works for sure. Also the high number of 56 different supplements tested and the deficit of repetition of the same supplement by different study groups makes a comparison and a meta-analysis difficult. Many of the forest plots presented in this meta-analysis only include one or two publications and are thus of low informative value for a meta-analysis. The doses used and age groups studied also varied between the different trials. Additionally, the supplement/vitamin/mineral supplies at baseline were rarely established and therefore, it is not clear whether the supplementation substituted an already existing deficiency and thus lead to positive results or served as an addition on top of the adequate supply. All of these differing factors between the studies play important roles in the outcome of the trials.

However, this paper is also characterized by some major strenghts like the comprehensive search strategy that resulted in 105 publications from all over the world with a total number of 6763 participants included in the meta-analysis. This search was performed with previously defined in- and exclusion criteria. To the knowledge of the author of this paper, this is the first meta-analysis of this broad extent comparing all the supplements used in RCTs with type 2 diabetics that could be found. Furthermore, this review is registered in the PROSPERO database „International prospective register of systematic reviews“.

10 Conclusion

This meta-analysis on trials with a study duration of at least 12 weeks shows that 24 out of the 56 supplements examined have a significant positive impact on glycaemic parameter in type 2 diabetics. Hence, supplement usage should be considered as a (complementary) therapy option for diabetes. However, caution should be exercised when it comes to vitamin/mineral combinations, zinc preparations, certain diabetes-specific ONS, and yeasts. So far, the numbers of trials examining the one and the same supplement are small. Thus to allow more precise recommendations on the use of supplements for the treatment of T2DM, further trials of the same study design should be performed with those supplements that showed first results indicating a considerable change of parameters into a positive direction such as probiotics, prebiotics, flaxseed, vitamin C and E, silymarin and berberine.

11 Abstract

Type 2 diabetes, formerly also called non-insulin-dependent diabetes mellitus or adult-onset diabetes, is characterized by an ineffectiveness of the body to use insulin (1). This type of diabetes accounts for approximately 90-95% of people with diabetes (2). There are several ways to achieve glycaemic control and improve insulin resistance such as diet, physical activity, weight reduction, oral glucose-lowering agents, subcutaneous insulin injections and possibly also the use of supplements (6). This systematic review and meta-analysis aimed to examine the influence of supplements on glycaemic parameters in adults suffering from diabetes mellitus type 2. The review included 122 randomized controlled trials examining type 2 diabetics after an intervention duration of at least 12 weeks. 105 of these studies were included in the meta-analysis. The statistical analysis was performed with the review manager 5.3 (Nordic Cochrane Center, Copenhagen).

Out of the 56 different supplements and combinations of supplements, 26 supplements and combinations lead to statistically significant changes in the outcome parameters. For example, HbA1c was significantly reduced through amino acids by 0.36% [95% confidence interval (CI) -0.67, -0.05], by 0.38% [95% CI -0.60, -0.16] through prebiotics, by 0.56% [95% CI -0.83, -0.29] through vitamin E, by 0.54% [95% CI -0.95, -0.12] through flaxseed, by 0.66% [95% CI -1.00, -0.33] through berberine and by 1.92% [95% CI -3.32, -0.51] through silymarin. Glucose levels were lowered by 0.40 mmol/L [95% CI -0.48, -0.32] through amino acids, by 0.83 mmol/L [95% CI -1.55, -0.10] through prebiotics, by 0.98 mmol/L [95% CI -1.18, -0.79] through flaxseed, by 0.76 mmol/L [95% CI -1.24, -0.29] through berberine, by 2.11 mmol/L [95% CI -3.69, -0.53] through silymarin, by 0.65 mmol/L [95% CI -1.07, -0.23] through vitamin C, by 0.85 mmol/L [95% CI -1.50, -0.21] through probiotics and by 0.74 mmol/L [95% CI -1.39, -0.09] through diacylglycerol. Vitamin C significantly decreased insulin by 2.66 μ U/mL [95% CI -4.51, -0.82] and HOMA-IR was significantly reduced through amino acids by 0.65 [95% CI -1.11, -0.20] and vitamin E by 0.55 [95% CI -0.65, -0.45].

At the same time, a significant increase in HbA1c was found through the supplementation of diabetes-specific oral nutritional supplements (+1.85% [95%

CI 1.02, 2.68]). A significant increase of 8.96 $\mu\text{mol/L}$ [95% CI 0.99, 16.93] was also found for the influence of zinc, vitamins and minerals on insulin. Furthermore, yeast supplementation significantly increased QUICKI (+0.02 [95% CI 0.01, 0.03]) and melatonin and zinc supplementation significantly increased C-Peptide levels (+0.38 ng/mL [95% CI 0.04, 0.72]).

Hence, it can be said that certain supplements such as probiotics, prebiotics, flaxseed, vitamin C and E, silymarin and berberine can have a positive influence on certain type 2 diabetics' glycaemic outcomes such as HbA1c, glucose, insulin and HOMA-IR. Thus, supplement usage should be considered as a (complementary) therapy option for diabetes. However, further trials of the same study design should be performed with those supplements that resulted in considerable decreases in parameters such as probiotics, prebiotics, flaxseed, vitamin C and E, silymarin and berberine in the first few trials.

12 Zusammenfassung

Typ 2 Diabetes, früher auch bekannt als nicht-insulinabhängiger Diabetes mellitus (NIDDM) oder Altersdiabetes, ist gekennzeichnet durch eine Unfähigkeit des Körpers, Insulin zu verarbeiten (1). Dieser Diabetestyp macht ca. 90-95% aller Diabetesfälle aus (2). Eine Ernährungsumstellung, Bewegung, Gewichtsreduktion, Blutzucker senkende Mittel, Insulinspritzen und vielleicht auch Nahrungsmittelsupplemente sind Möglichkeiten, den Blutzucker zu kontrollieren und die Insulinresistenz zu verbessern (6). Im Rahmen dieses systematischen Reviews/ dieser Meta-Analyse sollte der Einfluss von Nahrungsergänzungsmitteln auf die glykämischen Parameter erwachsener Typ 2 Diabetiker untersucht werden. 122 randomisierte kontrollierte Studien mit einer Mindestdauer von 12 Wochen wurden in den Review aufgenommen. 105 dieser Studien konnten in die Meta-Analyse eingeschlossen werden. Die statistische Analyse wurde mit dem Review Manager 5.3 (Nordic Cochrane Center, Kopenhagen) durchgeführt.

26 der 56 verschiedenen Supplementen und Kombinationen von Ergänzungsmitteln führten zu statistisch signifikanten Änderungen der Outcome-Parameter. Zum Beispiel wurde der Parameter HbA1c durch Aminosäuren um 0,36% [95% Konfidenzintervall (KI) -0,67; -0,05], durch Präbiotika um 0,38% [95% KI -0,60; -0,16], durch Vitamin E um 0,56% [95% KI -0,83; -0,29], durch Leinsamen um 0,54% [95% KI -0,95; -0,12], durch Berberin um 0,66% [95% KI -1,00; -0,33] und durch Silymarin um 1,92% [95% KI -3,32; -0,51] reduziert. Der Blutglukosespiegel wurde durch Aminosäuren um 0,40 mmol/L [95% KI -0,48; -0,32], durch Präbiotika um 0,83 mmol/L [95% KI -1,55; -0,10], durch Leinsamen um 0,98 mmol/L [95% KI -1,18; -0,79], durch Berberin um 0,76 mmol/L [95% KI -1,24; -0,29], durch Silymarin um 2,11 mmol/L [95% KI -3,69; -0,53], durch Vitamin C um 0,65 mmol/L [95% KI -1,07; -0,23], durch Probiotika um 0,85 mmol/L [95% KI -1,50; -0,21] und durch Diacylglycerol um 0,74 mmol/L [95% KI -1,39; -0,09] gesenkt. Vitamin C verringerte den Insulinlevel um 2,66 μ U/mL [95% KI -4,51; -0,82] statistisch signifikant und HOMA-IR wurde durch Aminosäuren um 0,65 [95% KI -1,11; -0,20] und durch Vitamin E um 0,55 [95% KI -0,65; -0,45] signifikant reduziert.

Gleichzeitig wurde jedoch der HbA1c-Wert durch Diabetes-spezifische orale Nahrungsmittelsupplemente signifikant erhöht (+1;85% [95% KI 1;02; 2;68]). Darüber hinaus führte die Supplementation von einer Kombination aus Zink, Vitaminen und Mineralstoffen zu einem Insulinanstieg um 8,96 $\mu\text{mol/L}$ [95% KI 0;99; 16;93]. Außerdem steigerten Hefen den QUICKI um 0,02 [95% KI 0.01; 0.03] und C-Peptid nahm durch eine Kombination von Melatonin und Zink um 0,38 ng/mL [95% KI 0.04; 0.72] zu.

Diese Ergebnisse erlauben die Schlussfolgerung, dass gewisse Supplemente wie Pro- oder Präbiotika, Leinsamen, Vitamin C oder E, Silymarin und Berberin einen positiven Einfluss auf bestimmte glykämische Parameter diabetischer Patienten wie HbA1c, Blutzucker, Insulin und HOMA-IR haben können. Nahrungsergänzungsmittel sollten daher als (zusätzliche) Therapiemöglichkeit für Diabetes in Erwägung gezogen werden. Allerdings sollten noch weitere Studien desselben Studiendesigns mit denjenigen Supplementen, die bis jetzt zu bedeutenden Abnahmen geführt haben, wie Pro- und Präbiotika, Leinsamen, Vitamin C und E, Silymarin und Berberin, durchgeführt werden.

14 Appendix

The following pages summarize the non-significant forest plots of all the supplements for the 9 different parameters examined.

14.1 HbA1c

Figure 71: Forest plot for HbA1c after anthocyanin supplementation vs. control.

Figure 72: Forest plot for HbA1c after antioxidant supplementation vs. control.

Figure 73: Forest plot for HbA1c after Caiapo supplementation vs. control.

Figure 74: Forest plot for HbA1c after chromium supplementation vs. control.

Figure 75: Forest plot for HbA1c after cinnamon supplementation vs. control.

Figure 76: Forest plot for HbA1c after cranberry extract supplementation vs. control.

Figure 77: Forest plot for HbA1c after DBCare supplementation vs. control.

Figure 78: Forest plot for HbA1c after EPA supplementation vs. control.

Figure 79: Forest plot for HbA1c after EPA and DHA supplementation vs. control.

Figure 80: Forest plot for HbA1c after fish oil supplementation vs. control.

Figure 81: Forest plot for HbA1c after folate, B6 and B12 supplementation vs. control.

Figure 82: Forest plot for HbA1c after *G. biloba* L. leaf supplementation vs. control.

Figure 83: Forest plot for HbA1c after Korean red ginseng supplementation vs. control.

Figure 84: Forest plot for HbA1c after *M. charantia* supplementation vs. control.

Figure 85: Forest plot for HbA1c after magnesium and zinc supplementation vs. control.

Figure 86: Forest plot for HbA1c after magnesium supplementation vs. control.

Figure 87: Forest plot for HbA1c after mineral and vitamin supplementation vs. control.

Figure 88: Forest plot for HbA1c after ABM supplementation vs. control.

Figure 89: Forest plot for HbA1c after n-3 fatty acid and low-dose aspirin supplementation vs. control.

Figure 90: Forest plot for HbA1c after N. sativa supplementation vs. control.

Figure 91: Forest plot for HbA1c after Pancreas Tonic supplementation vs. control.

Figure 92: Forest plot for HbA1c after probiotic supplementation vs. control.

Figure 93: Forest plot for HbA1c after Q10 supplementation vs. control.

Figure 94: Forest plot for HbA1c after resveratrol supplementation vs. control.

Figure 95: Forest plot for HbA1c after selenium supplementation vs. control.

Figure 96: Forest plot for HbA1c after soy supplementation vs. control.

Figure 97: Forest plot for HbA1c after DJC supplementation vs. control.

Figure 98: Forest plot for HbA1c after tea extract supplementation vs. control.

Figure 99: Forest plot for HbA1c after vitamin C and E supplementation vs. control.

Figure 100: Forest plot for HbA1c after whortleberry supplementation vs. control.

Figure 101: Forest plot for HbA1c after yeast supplementation vs. control.

Figure 102: Forest plot for HbA1c after zinc and flaxseed oil supplementation vs. control.

Figure 103: Forest plot for HbA1c after vitamin D supplementation vs. control.

Figure 104: Forest plot for HbA1c after vitamin C supplementation vs. control.

14.2 Glucose

Figure 105: Forest plot for glucose after alpha-lipoic acid supplementation vs. control.

Figure 106: Forest plot for glucose after anthocyanin supplementation vs. control.

Figure 107: Forest plot for glucose after antioxidant supplementation vs. control.

Figure 108: Forest plot for glucose after vitamin B6 supplementation vs. control.

Figure 109: Forest plot for glucose after chromium supplementation vs. control.

Figure 110: Forest plot for glucose after cinnamon supplementation vs. control.

Figure 111: Forest plot for glucose after cranberry extract supplementation vs. control.

Figure 112: Forest plot for glucose after DBCare supplementation vs. control.

Figure 113: Forest plot for glucose after EPA supplementation vs. control.

Figure 114: Forest plot for glucose after EPA and DHA supplementation vs. control.

Figure 115: Forest plot for glucose after fish oil supplementation vs. control.

Figure 116: Forest plot for glucose after folate, B6 and B12 supplementation vs. control.

Figure 117: Forest plot for glucose after garlic supplementation vs. control.

Figure 118: Forest plot for glucose after ginger supplementation vs. control.

Figure 119: Forest plot for glucose after Korean red ginseng supplementation vs. control.

Figure 120: Forest plot for glucose after *M. charantia* supplementation vs. control.

Figure 121: Forest plot for glucose after magnesium supplementation vs. control.

Figure 122: Forest plot for glucose after magnesium and zinc supplementation vs. control.

Figure 123: Forest plot for glucose after melatonin and zinc supplementation vs. control.

Figure 124: Forest plot for glucose after mineral and vitamin supplementation vs. control.

Figure 125: Forest plot for glucose after ABM supplementation vs. control.

Figure 126: Forest plot for glucose after N. sativa supplementation vs. control.
