## Diplomarbeit

Titel der Diplomarbeit

# „Heuristic Solution Approaches for the Covering Tour Problem" 

Verfasser<br>Patrick Kubik

angestrebter akademischer Grad
Magister der Wirtschaftswissenschaften

Wien, im Dezember 2007

Studienkennzahl It. Studienblatt:<br>Studienrichtung It. Studienblatt:<br>Betreuer:

A 157
Internationale Betriebswirtschaft
Univ.-Doz. Dr. Karl Dörner

# Für meine Eltern, die mich immer unterstützt und stets an mich geglaubt haben. 

Weiters möchte ich mich bei Univ.-Doz. Dr. Karl Dörner für die hervorragende Betreuung bedanken.

Besonders möchte ich mich bei Kerstin für Ihr Verständnis und Ihre Unterstützung bedanken. Ohne Dich hätte ich es nicht geschafft.

## Eidesstattliche Erklärung

Ich erkläre hiermit an Eides Statt, dass ich die vorliegende Arbeit selbständig und ohne Benutzung anderer als der angegebenen Hilfsmittel angefertigt habe. Die aus fremden Quellen direkt oder indirekt übernommenen Gedanken sind als solche kenntlich gemacht.

Die Arbeit wurde bisher in gleicher oder ähnlicher Form keiner anderen Prüfungsbehörde vorgelegt und auch noch nicht veröffentlicht.

Wien, im Dezember 2007

Patrick Kubik

## List of abbreviations

| ACO | Ant Colony Optimization |
| :--- | :--- |
| ACS | Ant Colony System |
| AS | Ant System |
| CTP | Covering Tour Problem |
| CTACS | Covering Tour Ant Colony System |
| GACS | GENI Ant Colony System |
| GENI | General Insertion |
| M\&S | Marchiori and Steenbeek |
| mGENI | multi-start GENI |
| SCACS | Set Covering Ant Colony System |
| SCP | Set Covering Problem |
| TSP | Traveling Salesman Problem |
| US | Unstring and String |

## List of sets, parameters and variables

| $a_{i j}$ | $\left\{\begin{array}{lc} 1 & \text { if column } j \text { cov ers row } i \\ 0 & \text { otherwise } . \end{array}\right.$ |
| :---: | :---: |
| $A=\left(a_{i j}\right)$ | $m \times n$ 0-1 matrix |
| $b_{k}$ | Number of rows that can be covered by vertex $k$ |
| c | Covering distance parameter |
| $c_{i j}$ | Cost of an edge ( $i, j$ ) |
| $c^{\prime}{ }_{i j}$ | Modified cost of an edge ( $i, j$ ) |
| $c_{j}$ | Cost of a column $j$ |
| $c_{k}$ | Cost of inserting vertex $k$ |
| $C=\left(c_{i j}\right)$ | Distance matrix |
| $C^{\text {bs }}$ | Length of the best-so-far tour $T^{\text {bs }}$ (ACS) |
| $C^{\text {GENI }}$ | Cost of a GENI tour |
| $C^{n n}$ | Cost of a nearest-neighbor tour |
| $C^{S C P}=\left(c_{j}\right)$ | $n$-dimensional cost vector |
| $\operatorname{draw}(J)$ | Random variable determining next insertion (GACS) |
| E | Set of edges on a graph |
| $f\left(c_{k}, b_{k}\right)$ | Function determining the covering criterion |
| $G$ | Graph |
| $H, H^{\prime}, H^{*}$ | Final, intermediate and best-so-far tour (GENIUS) |
| $I$ | Number of iterations (GACS, SCACS) |
| $i \in M=\{1, \ldots . ., n\}$ | Set of $n$ rows |
| $J$ | Random variable determining the next move (ACS) |
| $j \in N=\{1, \ldots . ., m\}$ | Set of $m$ columns |
| $m_{a}$ | Number of ants |
| $M^{k}$ | Memory of ant $k$ |
| $N_{i}^{k}$ | Neighborhood of ant $k$ at vertex $i$ |
| $N_{p}(v)$ | Neighborhood of vertex v with $p$-closest neighbors |
| $O$ | Effect of the problem size on an algorithm's usage |

|  | of computational resources |
| :---: | :---: |
| $p$ | Sets the size of $N_{p}(v)$ (GENIUS) |
| $p_{i j}^{k}$ | Probability of ant $k$ choosing the edge from vertex to $j$ |
| $p_{j}^{k}$ | Probability of ant $k$ choosing column $j$ |
| $S$ | Subset of an unfinished solution |
| $S^{\text {bs }}$ | Best-so-far solution (ACS SCP) |
| $S^{\text {GENI }}$ | Number of ranks (GACS) |
| $S_{k}$ | Partial solution obtained by ant $k$ (ACS SCP) |
| $S_{\ell}$ | Covering set of a vertex $v_{\ell} \in W$ |
| $T^{\text {bs }}$ | Best-so-far tour in ACS |
| $T^{\text {GENI }}$ | Random variable determining next move (GACS) |
| $T^{k}$ | Tour generated by ant $k$ |
| $q$ | Random variable uniformly distributed in [0,1] |
| $q_{0}$ | Sets the bar for the best choice (ACO) |
| $v_{k} \in T$ | Set of vertices that must be visited |
| $v_{k} \in V$ | Set of vertices on a graph |
| $\nu_{\ell} \in W$ | Set of vertices that must be covered |
| $v_{0}$ | Starting point on a tour |
| $x_{i j}$ | $\left\{\begin{array}{l} 1 \quad \text { if edge }(i, j) \text { is used }, \\ 0 \\ \text { otherwise } . \end{array}\right.$ |
| $y_{k}$ | $\left\{\begin{array}{lc} 1 & \text { if vertex } k \text { is on the tour } \\ 0 & \text { otherwise } \end{array}\right.$ |
| $z, z^{\prime}, z^{*}$ | Cost of the final, intermediate and best-so-far tour (GENIUS) |
| $z^{\text {bs }}$ | Best-so-far cost (ACS SCP) |
| $z_{G R}$ | Cost of a greedy solution |
| $\alpha$ | Controls pheromone deposit in global update (ACS) |
| $\beta$ | Controls heuristic influence (ACO) |

| $\delta_{\ell k}$ | $\left\{\begin{array}{lc}1 & \text { if vertex } \ell \text { is covered by } k, \\ 0 & \text { otherwise. }\end{array}\right.$ |
| :--- | :--- |
| $\gamma$ | Modifies the relative influence of pheromone values $\eta_{i j}$ <br> Heuristic value of edge $(i, j)$ |
| $\eta_{j}$ | Heuristic value of column $j$ |
| $\rho$ | Controls pheromone deposit in local update (ACS) |
| $\tau_{0}$ | Initial pheromone value |
| $\tau_{i j}$ | Pheromone trail on edge $(i, j)$ |
| $\Delta \tau_{i j}^{b s}$ | Pheromone deposited in global update (ACS) |
| $\Delta \tau_{i j}^{k}$ | Relative amount of pheromone on edge $(i, j)$ |
| $\tau_{i j}^{R}$ | Pheromone trail of column $j$ |
| $\tau_{j}$ | Controls pheromone influence (AS) |
| $\Delta \tau_{j}^{b s}$ |  |

## 1 Introduction

This section outlines the importance of logistics and combinatorial optimization in a profit-orientated society and very briefly discusses the relevant literature. Finally, it gives a short outlook on the remaining contents of the diploma thesis.

### 1.1 Logistics and transportation

The globalization of world economy, increasing dynamics of global markets and of customer requirements as well as the rapid development of Asian economies have awarded logistics and its associated costs a completely new economical importance. Companies have to monitor these costs with increasing precaution because "distribution costs account for almost half of the total logistics costs and in some industries, such as food and drink business, distribution costs can account for up to $70 \%$ of the value added costs of goods" [5]. Only those companies taking advantage of global cost synergies while improving their customer service and therefore increasing their logistical capacity are able to remain competitive.
One example, to what extent the importance and value of business logistics especially in terms of transportation - has grown during the last few years, is shown by the fact that Maersk Line, the largest container shipping company worldwide, operates up to 11.5 million containers with a total value of approximately 250 million US-Dollars per year. The economic wealth realized through these transports exceeds the worldwide budget for foreign aid about five times. During the last year, 100 million containers were shipped from seaports around the world and forecasts for the next ten years lead to the assumption that this number will at least double. Three billion ton-kilometers by train, road and air transport EU wide in 2005 document the increasing importance of cargo transportation [22].
On the other side, the role of logistics - particularly of transportation - in the regional sector is becoming increasingly important. The key role of public transportation in a nation's economy used to result in governmental ownership of public transportation companies, e.g. Deutsche Bahn in Germany. The same can be said about postal delivery services. However, recent developments,
especially in Central Europe, have shown a trend for these companies to go public, reducing the social component of their services by closing down nonprofitable branches and service lines mainly in rural regions. Still, the companies' interest lies in maintaining a certain service level which leads to a trade-off between customer satisfaction and profit.
Another interesting field of logistic and transportation is the effective service distribution of non-profit health care organizations in industrial countries as well as in third world countries and disaster areas.

### 1.2 Combinatorial optimization

The majority of problems in logistics and transportation are difficult and can be modeled as combinatorial problems. They usually deal with maximizing or minimizing an objective under certain constraints. One of the most important factors in fields like logistics, operations research or applied mathematics is decision making. Algorithmic approaches and computational complexity theory help to improve and optimize these decisions. When dealing with NP-hard ${ }^{1}$ problems, combinatorial optimization offers three possible solution techniques to solve the problem: enumerative methods that lead to guaranteed optimal solutions but require a lot of resources, approximation algorithms running in polynomial time and heuristics with some a priori uncertainty concerning solution quality and processing time [1]. All these methods examine the normally large solution spaces of a combinatorial optimization problem and reduce it by effective exploration.

### 1.3 The Covering Tour Problem

The Covering Tour Problem (CTP) is one of the combinatorial optimization problems that can be applied to these real world problems. There is a given set of vertices (e.g., cities) that have to be visited. Further vertices exist that can be visited. A third set of vertices may not be visited but must be covered by a city that is visited. Covering means that a vertex that is visited is within a predefined distance of a city to be covered. The objective is to find the shortest

[^0]tour so that all covering and visiting requirements are met. Literature and solution methods on this problem are scarce. I filled a part of this gap by applying heuristic and meta-heuristic approaches to the problem. I performed extensive tests to find optimal parameter settings and to determine the best solution approach.

### 1.4 Layout

The diploma thesis is organized as follows. Section 2 describes in detail the CTP along with its model, applications and components. Section 3 is dedicated to the chosen solution approaches for the CTP such as Ant Colony Optimization (ACO) and a combination of a general insertion and post-optimization algorithm (GENIUS) and a set covering algorithm (PRIMAL1). Test problems and their computational results are discussed in section 4 while section 5 summarizes the findings. Appendix $A$ and $B$ illustrate test results.

## 2 The Covering Tour Problem

Section 2 presents the CTP with a small example and states the model. Then some real world applications of the CTP are described. In addition, the relationship of the CTP with the Traveling Salesman Problem (TSP) and the Set Covering Problem (SCP) is emphasized.

### 2.1 Description

First an example ${ }^{2}$ :

The national postal service has decided to cut costs by reducing the number of local post offices in the countryside. Only those post offices in more populated towns should remain and operate as distribution centers for rural villages without post offices. In order to sustain the present service level at lower costs, the logistic department of the national post company has decided to assign

[^1]each town with a number of small villages that used to have a post office and a number of even smaller villages that used to be serviced by those offices. A town office should use a vehicle to maintain postal service for the appointed region. This vehicle should be loaded with post destined for the region as well as with postal goods (stamps, envelopes, etc.) needed by the population of the rural villages at the town's post office every morning. Then the vehicle must visit a certain number of villages (e.g.: villages with population above a certain limit or where frequent need of postal service is known from the past). It can visit some additional villages to ensure that the rural population is able to reach the vehicle without too much effort. However every village is only visited once each day. At each stop the population can collect their post and purchase goods needed. They also hand in their mail. After the vehicle has visited all mandatory destinations it should return to the post office.

A number of transportation problems can be found in this example. First, the decision to close some and continue other offices is a location problem. Loading the vehicle is a Bin Packing problem and delivering and collecting post is a Pickup and Delivery problem (in our example assembly with time windows). However, in order to focus on the CTP, we neglect the vehicle's capacity constraints and focus on the objective of covering all obliged targets at minimum cost.

The CTP is defined on a complete undirected graph $G=(V \cup W, E)$ with a set of vertices $V \cup W$ where $V=\left\{v_{0}, \ldots ., v_{n}\right\}$ is a set of vertices that can be visited, $W$ defines the set of vertices that have to be covered by the tour and $E=\left\{\left(v_{i}, v_{j}\right): v_{i}, v_{j} \in V \cup W, i<j\right\}$ is the set of edges. "Covered by the tour" means that any vertex $v_{\ell} \in W$ has to lie within a predefined distance of a vertex on the tour. The set $V$ includes the subset $T$. The subset $T \subset V$ determines the set of vertices whose visit is obligatory. Vertex $v_{0}$ represents the depot and belongs to the set $T \subset V\left(v_{0} \in T\right)$. The distance or travel time matrix $C=\left(c_{i j}\right)$ indicates the edge length between all vertices $(V \cup W)$ in the edge set $E=\left\{\left(v_{i}, v_{j}\right): v_{i}, v_{j} \in V \cup W, i<j\right\}$ while satisfying the triangle inequality. The triangle inequality theorem states that for any triangle, the
length of a given side must be shorter than the sum of the other two but greater than the difference between these two. This theorem holds for all Euclidean spaces.

The parameter $c$ specifies the allowed maximum covering distance or in other words the maximum length of an edge between an unvisited vertex of set $W$ and the nearest visited vertex of set $V$.

The solution to the CTP is a minimum length tour or Hamiltonian cycle [14]. The tour starts and ends at the depot $\left(v_{0} \in T\right)$. The tour is defined by a certain subset (often referred to as $S$ ) of $V$ so that all vertices of the subset $T$ (all vertices that have to be visited) are visited by the tour and each vertex of set $W$ (all vertices that have to be covered) lies within a predetermined distance $c$ of a vertex belonging to the tour. The assumption that the depot ( $v_{0} \in T$ ) does not cover all vertices of set $W$ must also hold. Consequently, if the covering distance $c$ equals zero, the CTP reduces to a TSP because then naturally every vertex from the set $W$ becomes a member of the vertex subset $T$ and has to be visited directly. Determining the Hamiltonian path or minimum length tour is classified as an NP-hard problem and a feasible solution can not always be found.

Figure 1 shows a possible solution to the CTP. Note that the coverage circles around each vertex of set $V$ all have the same radius $c$ which is the predetermined covering distance.

Figure 1: A possible solution to the CTP ${ }^{3}$

If the predetermined covering distance $c$ of every vertex equals zero, every vertex of set $W$ corresponds to a vertex of set $V$. The CTP then reduces to a TSP (Figure 2).

Figure 2: CTP with $c=0$ reduces to TSP

[^2]
### 2.2 Brief literature review

Not a lot of literature concerning the CTP exists today. Gendreau et al. [14] give a good discussion of papers related to the problem before 1997 including the first actual formulation by Current and Schilling [6] under the name Covering Salesman Problem. Gendreau et al. [14] are also the first to formulate a model and an exact algorithm in order to solve the problem. Hachida et al. [16] introduce the multi-vehicle Covering Tour Problem (m-CTP) and apply the heuristic used in [14]. They also present modified versions of the sweep and savings algorithms. Jozefowiez et al. [18] tackle the bi-objective CTP by combining a multi-objective evolutionary algorithm with a branch-and-cut algorithm.

### 2.3 The CTP model

The CTP can be formulated as a linear integer program. To start with, some binary variables have to be defined.

For $v_{k} \in V$ the binary variable $y_{k}$ equals 1 , if a vertex $v_{k}$ of the vertex set $V$ is visited. Otherwise the variable $y_{k}$ equals 0 . Of course, if $v_{k} \in T$, then $y_{k}$ must always equal 1 .
For $v_{i}, v_{j} \in V$ and $i<j$, the binary variable $x_{i j}$ equals 1 for every edge $\left(v_{i}, v_{j}\right)$ visited by the tour. Otherwise the variable $x_{i j}$ equals 0 .

The binary coefficient $\delta_{\ell k}$ equals 1 if and only if $v_{\ell} \in W$ can be covered by $v_{k} \in V$. This means that the distance $c_{\ell k}$ between $v_{\ell} \in W$ (the vertex that has to be covered) and $v_{k} \in V$ (the vertex that covers $v_{\ell} \in W$ ) is smaller than the predetermined covering distance $c$. Otherwise the coefficient $\delta_{\ell k}$ equals 0 . The subset $S_{\ell}=\left\{v_{k} \in V \mid \delta_{\ell k}=1\right\}$ detects all vertices of the set $V$ capable of covering a vertex $v_{\ell} \in W$ within the predetermined covering distance for every $v_{\ell} \in W$. The condition $\left|S_{\ell}\right| \geq 2$ for all $v_{\ell} \in W$ and the infeasibility of the degenerate tour ( $v_{0}$ ) are also necessary assumptions.

The CTP can be stated as:

Minimize $\quad \sum_{i=0}^{n-1} \sum_{j=i+1}^{n} c_{i j} x_{i j}$

Subject to

$$
\begin{array}{cc}
\sum_{v_{k} \in S} y_{\ell} \geq 1 & \forall v_{\ell} \in W, \\
\sum_{i<k} x_{i k}+\sum_{j>k} x_{k j}=2 y_{k} & \forall v_{k} \in V, \\
\sum_{i} x_{i j} \geq 2 y_{k} & (S \subset V, 2 \leq|S| \leq n-2, \\
v_{i} \in S, v_{j} \in V \backslash S \\
\text { or } v_{j} \in S, v_{i} \in V \backslash S & \left.T \backslash S \neq \varnothing, v_{k} \in S\right), \\
x_{i j} \in\{0,1\} & \forall 1 \leq i<j \leq n, \\
y_{k} \in\{0,1\} & \forall v_{k} \in V \backslash T, \\
y_{k}=1 & \forall v_{k} \in T .
\end{array}
$$

The objective function (2.1) minimizes the total distance traveled to reach all $v_{k} \in T$ and to cover all $\nu_{\ell} \in W$.

The first constraint (2.2) demands coverage for each vertex $v_{\ell} \in W$ by the tour. Constraint (2.3) ensures that each vertex $v_{k} \in V$ is visited only once and that it is entered and left again while constraint (2.4) eliminates sub-tours by making sure that, for every subset $S$ of $V$ there are at least two edges between any subset $S$ and the set of vertices $V \backslash S$ (set $\vee$ without vertices of subset $S$ ) such that subset $T \backslash S \neq \varnothing$ and subset $S$ contains a vertex $v_{t} \in S$.

Constraints (2.5), (2.6) and (2.7) ensure that variables $x_{i j}$ and $y_{k}$ are binary, the model is integer and $y_{k}$ always equals 1 if $v_{k} \in T$.

### 2.4 Applications

One application of the CTP occurs in the health care sector concerning the deployment of a mobile medical facility in developing countries [17]. Traveling health care teams can only access a limited number of villages. This may be due to infrastructural restrictions like non-existing roads, resource restrictions like the tank size of the vehicle or governmental rule setting. Of course, the cost factor is always a barrier for non-profit organizations too. However, the routes of the health care teams have to be chosen in such a way that every person in need of medical service has the possibility to reach one of the villages integrated on the team's tour by foot. Solving the CTP enables the construction of efficient routes for these health care teams, reducing costs by minimizing traveling distances and therefore petrol consumption, minimizing traveling time and therefore increasing the time for medical service as well as maximizing the patient coverage.

The design of bi-level transportation networks is another common application where the tour chosen to reach all $v_{k} \in T$ and to cover all $v_{\ell} \in W$ represents the route of any primary vehicle and all $v_{\ell} \in W$ are within covering distance [14]. One example would be to locate a number of regional distribution centers from a set of candidates for an express delivery service (such as DHL or UPS) in order to minimize the cost of distributing the objects to every region from a central distribution centre and vice versa collecting objects from the regional centers. The covering tour chosen represents the tour of a primary vehicle (e.g.: large truck) with the central distribution centre $v_{0}$ as depot and regional centers as vertices (all $v_{k} \in T$ and possibly some $v_{k} \in V \backslash T$ ) on the tour). On the secondary level the CTP does not consider how to distribute efficiently but ensures that the end customers of each regional centre lie within a reasonable covering distance (in the sense that a small delivery truck can reach all of them in one day and at minimum cost). The problem on the secondary level could then be solved as a separate TSP or vehicle routing problem.

Other real world applications are the postal service example in 2.1, the routing of aircrafts for overnight delivery systems where only cities with airports are visited and other cities within a maximal covering distance are supplied by ground transportation [6] or the design of computer networks where servers
are the vertices and the tour is a ring network to increase the reliability. The covering part should minimize the cost of connecting personal computers with their nearest server [7].

### 2.5 Components of the Covering Tour Problem

In order to solve the CTP, Gendreau, Laporte and Semet [14] classified it as a combination of the TSP and SCP. I chose to adopt this approach but used additional algorithms for these two problems which I combined in order to solve the CTP. In the next two sections a brief overview of these two problems follows.

### 2.5.1 The Traveling Salesman Problem

The TSP deals with the following problem:

A salesman wants to visit a number of clients at different locations, starting from his hometown. He wants to visit every client once and then return to his starting point. What sequence should he choose in order to minimize his total traveling distance?

The TSP is the most common form of all combinatorial optimization problems and qualifies as an NP-hard problem. The importance of the TSP is not due to the fact that millions of salesmen need a solution to their business problem but that a TSP can be applied to a great number of variations of combinatorial optimization and "every day" problems. There are symmetric and asymmetric formulations of the TSP but as the focus of this chapter lies on showing the components of the CTP which is discussed only for symmetric problems, the symmetric TSP will be introduced. An example for an asymmetric TSP would be route optimization with one-way streets.

The objective is to find a sequence of vertices $V=\left\{v_{0}, \ldots, v_{n}\right\}$ on a weighted graph $G=(V, E)$ that results in the shortest tour or Hamiltonian cycle by visiting each vertex of $V$ exactly once and then returning to the starting point. $E=\left\{\left(v_{i}, v_{j}\right): v_{i}, v_{j} \in V, i<j\right\}$ determines the edge set. Edges are used to
connect the vertices and their weights are given by a distance or travel time matrix $C=\left(c_{i j}\right)$.

As already mentioned the TSP is one of the most important problems in combinatorial optimization. Therefore, in the past three decades numerous papers on various solution methods to the TSP have been published. Exact, heuristic and meta-heuristic approaches have been developed. Some will be introduced later on when solution approaches for the CTP are described.

The TSP can be stated as [8]:

Minimize $\quad \sum_{i<j} c_{i j} x_{i j}$
Subject to

$$
\begin{array}{lr}
\sum_{i<k} x_{i k}+\sum_{j>k} x_{k j}=2 & (k \in V), \\
\sum_{v_{i}, v} \in S \\
x_{i j} \leq|S|-1 & S \subset V, 3 \leq|S| \leq n-3,  \tag{2.11}\\
x_{i j} \in\{0,1\} & (i \in V, j \in V) .
\end{array}
$$

The objective function (2.8) minimizes the tour length under the condition that vertices $V=\left\{v_{0}, \ldots ., v_{n}\right\}$ are only visited once and that each vertex is entered and left (2.9). Equation (2.10) eliminates subsets (sub-tours). The binary variable $x_{i j}$ equals 1 if edge $\left(v_{i}, v_{j}\right)$ belongs to the tour. Otherwise the variable $x_{i j}$ equals 0 (2.11).

### 2.5.2 The Set Covering Problem

Just like the TSP, the SCP qualifies as an NP-hard combinatorial optimization problem with applications in facility location and vehicle routing. The objective is to cover a number of rows with a set of columns at minimum cost.
It can be defined by a $m \times n 0-1$ matrix $A=\left(a_{i j}\right)$. To solve the SCP, a subset of columns $j \in N=\{1, \ldots ., m\}$ that covers all the rows $i \in M=\{1, \ldots ., n\}$ in $A$ with
minimal total costs has to be derived. Covering costs are given by an $n$ dimensional cost vector $C^{S C P}=\left(c_{j}\right)$, where $c_{j}$ is the cost of selecting column $j$ in matrix $A$. A row $i \in M=\{1, \ldots ., n\}$ is covered by a column $j \in N=\{1, \ldots ., m\}$ if $a_{i j}$ equals 1 .

A good example is the problem of assigning factories producing goods to customers in order to satisfy their demands with minimal costs. Another example is airline crew scheduling.

The SCP can be stated as:

Minimize

$$
\begin{equation*}
\sum_{j \in N} c_{j}^{x} j \tag{2.12}
\end{equation*}
$$

Subject to

$$
\begin{array}{ll}
\sum_{j \in N} a_{i j} x_{j} \geq 1 & \forall i \in M, \\
x_{j} \in\{0,1\} & \forall j \in N . \tag{2.14}
\end{array}
$$

The objective function (2.12) minimizes the total cost of covering all the rows in $N$. (2.13) ensures that every row is covered by at least one column and (2.14) ensures integrality.
Again, solution methods will be introduced later when tackling the CTP but to highlight the relation between SCP and CTP, some adjustments have to be made. The objective function (2.12) changes from $\sum_{j \in N} c_{j} x_{j}$ to $\sum_{v_{k} \in V} c_{k} y_{k}$. The set $v_{k} \in V=\left\{v_{0}, \ldots ., v_{n}\right\}$ with subset $T \subseteq V$ from the CTP replaces the set of columns $j \in N=\{1, \ldots, m\}$ in the SCP. The binary variable $x_{j}$ becomes $y_{k}$. In the SCP the binary variable $x_{j}$ equals 1 if a column is chosen to cover one or more rows. In the CTP $y_{k}$ equals 1 if a vertex $v_{k} \in V$ is included into the tour. The variable $a_{i j}$ is the cost of choosing column $x_{j}$ in the SCP. This is the cheapest cost $c_{k}$ of inserting vertex $v_{k} \in V$ in the tour in the CTP. Constraint (2.13) substitutes $\sum_{j \in N} a_{i j} x_{j} \geq 1$ with $\sum_{v_{k} \in S_{\ell}} y_{k} \geq 1$ for the set $v_{\ell} \in W$ which stands for the
set of rows $i \in M=\{1, \ldots, n\}$ in the SCP. The parameter $S_{\ell}$ equals the covering set $S_{\ell}=\left\{v_{k} \in V \mid \delta_{\ell k}=1\right\}$ for every $v_{\ell} \in W$ of the CTP.

In addition, the value of the binary variable $y_{k}$ for all vertices associated with subset $T \subseteq V$ (determining the set of obligatory vertices) equals 1 which means that some columns are always chosen.

## 3 Solution approaches

This section introduces the concept of ACO and describes in detail the idea of the Ant Colony System (ACS) metaheuristic. Furthermore, the GENIUS algorithm for solving TSPs is specified. After that follows a presentation of the set covering heuristic PRIMAL1. Finally, the pieces are put together in order to solve the CTP and the H -1-CTP heuristic, a combination of GENIUS and PRIMAL1, as well as CTACS, a combination of GENI Ant Colony System (GACS) [19] and an ACS for the SCP (SCACS) [20] are introduced.

### 3.1 Ant colony optimization ${ }^{4}$

ACO is a nature inspired metaheurisitic for solving computational and combinatorial problems that deal with finding the shortest path on graphs. The solution strategy is based on the swarm-like behavior of real ants foraging for food.

### 3.1.1 Real ants

The lack of vision that characterizes the majority of ant species forces the individual insect to communicate with its colony by producing chemicals called pheromones. Ants can sense these pheromones and use them as a form of indirect communication called stigmergy [12]. An individual ant may only perform simple tasks. However, a whole colony of ants - a highly structured social organization - is able to fulfill complex tasks by coordinating their

[^3]activities by modifying their environment. A particularly important chemical is the trail pheromone that helps ants to move in the surrounding area of their nest. Experiments like the double bridge experiment [9] and [15] show the behavior of ants foraging for food.

Figure 3: Double bridge experiment: (a) equal length and (b) double length

As figure 3 shows, the nest and the food source are connected by two bridges equally long in instance (a) and one longer than the other in instance (b). Initially, no pheromone trails are laid. Ants proceed from their nest to the first intersection and, in both cases (a) and (b), randomly choose one of the two bridges with nearly the same probability while searching for food. Still, the number of ants on each connection differs due to random fluctuation. Ants cross the bridges laying pheromone trails on the ground. On the way back from the food source to the nest, the amount of chemicals produced depends on the quality of the food, consisting of food quantity and the distance between nest and source. Over time, the pheromones laid in this manner evaporate. When other ants search for food, they will follow the pheromone trails and therefore abandon their random behavior more and more. In (a), one connection's pheromones dominate the other's due to initial fluctuation and after some time, all ants choose the same path to the food source. In (b), the pheromone trail on the shorter path becomes stronger than on the longer one because ants using the shorter branch arrive earlier at the food source. The usage is more frequent and the laying exceeds evaporation by far. More ants follow the most attractive path leading to less pheromone deposit on the longer path. After some time, the trails on the longer path disappear and all ants eventually choose the shorter path (see figure 4).

Figure 4: The effect of stigmergy during food foraging

### 3.1.2 Artificial ants and ACO algorithms for the TSP

In ACO, artificial ants simulate the trail laying and following procedure of real ants in order to build solutions to an optimization problem. Dorigo and Stützle [12] call ants stochastic constructive procedures that incrementally build solutions by performing a randomized walk on a completely connected graph and by adding opportunely defined solution components to a partial solution under construction. $m_{a}$ ants construct solutions to a problem which can be defined on a completely connected construction graph $G=(C, L)$. $C=\left\{c_{0}, c_{1}, \ldots . ., c_{n}\right\}$ represents the components and $L$ is a set of connections between these components on the graph. An ant $k$ 's move from one component $c_{i}$ to another $c_{j}$ is subject to a probabilistic decision depending on heuristic information $\eta_{i j}$ and pheromone trail $\tau_{i j}$. After finishing a move on the graph, ant $k$ stores the found solution in its memory $M^{k} . M^{k}$ can be used to build feasible solutions, compute heuristic values $\eta_{i j}$ and to evaluate the solution found by updating the pheromone $\tau_{i j}$ on the connections visited depending on their quality. If a pre-specified termination condition $e^{k}$ is met, ant $k$ ends the construction process.

Figure 5 demonstrates the general framework of ACO algorithms with a pseudo-code. ConstructAntsSolution controls the construction moves of the colony. UpdatePheromones manages the value of new pheromones and evaporation. DaeomonActions are optional measures including local search and global pheromone update.

## procedure ACOMetaheuristic

## ScheduleActivities

ConstructAntsSolutions
UpdatePheromones
DaemonActions
end-ScheduleActivities
end-procedure
Figure 5: ACO pseudo-code

The difference between global and local update will become clear in the next section, where the functionality of ACO algorithms applied to the TSP is demonstrated. The focus lies on the Ant System (AS) and especially the ACS algorithm. Also, other important ACO algorithms, namely Elitist Ant System, Ant-based Ant System and Max-Min Ant System will be addressed. Since I will implement ACO for the TSP (as part of the CTP), I will refer to components $C=\left\{c_{1}, c_{2}, \ldots ., c_{n}\right\}$ as vertices (or cities) $V=\left\{v_{0}, \ldots ., v_{n}\right\}$ and to the connection set $L$ as edge set $E=\left\{\left(v_{i}, v_{j}\right): v_{i}, v_{j} \in V, i<j\right\}$. In all ACO algorithms, each edge is assigned a pheromone trail $\tau_{i j}$ and a heuristic value $\eta_{i j}$ (e.g. $\eta_{i j}=1 / c_{i j}$ the reciprocal of the distance between two cities $i$ and $j$ ) during solution construction. The initial pheromone value $\tau_{0}$ is set to $1 / n C^{n n}$ with $n$ being the number of cities and $C^{n n}$ the length of a nearest-neighbor tour. Following the construction process, each ant is placed at an initial city based on some criterion, then uses $\tau_{i j}$ and $\eta_{i j}$ in the probabilistic manner described above to iteratively visit all the vertices and finally returns to the starting vertex. Afterwards, the ant passes through the found solution in the opposite order to assign the edges used with pheromone values. Furthermore, daemon actions may be executed.

### 3.1.3 Ant System

The first algorithm imitating the foraging behavior was AS, introduced in [10] and [11]. At first there were three versions, two with pheromone updates directly after a move from one city to the next (ant-density and ant-quantity) which performed rather poorly in comparison to the third one where pheromone updates were related to the tour quality and executed after all ants had finished constructing (ant-circle). The latter is now known as AS. It consists of solution construction and pheromone update. An iteration draws the following pattern: $m_{a}$ ants are randomly positioned at different starting points. An ant $k$ moves from city $i$ to $j$ according to the probabilistic state transition rule:
$p_{i j}^{k}=\frac{\left.\left\lfloor\tau_{i j}\right\rfloor^{\zeta} \eta_{i j}\right\rfloor^{\beta}}{\sum l \in N_{i}^{k}\left[\tau_{i l}\right]^{\zeta}\left[\eta_{i l}\right]^{\beta}}, \quad \forall j \in N_{i}^{k}$,
$p_{i j}^{k}$ is the probability of ant $k$ choosing edge $(i, j)$ to move from city $i$ to $j$. As mentioned above, $\eta_{i j}=1 / c_{i j}$ is the heuristic information value, $\zeta$ and $\beta$ are parameters determining the influence of pheromone values $\tau_{i j}$ and heuristic information on the decision which city to visit next. $N_{i}^{k}$ is the feasible neighborhood of ant $k$ defined by not yet visited cities available at city $i$. If $\zeta=0$, only the heuristic information and therefore the closest city is taken into account. If $\beta=0$, only pheromone values determine the move and stagnation may occur.
Before every move of ant $k$, the probability $p_{i j}^{k}$ has to be calculated for all candidate edges and is then added up to a cumulative probability. Then the so called Roulette Wheel selection is performed by generating a random number between 0 and the probability sum of all possible moves ( $\sum p_{i j}^{k}$ ) and selecting a move if the corresponding cumulative probability range contains that number. Figure 6 demonstrates this procedure with a small example:

|  | probability | cum. probability |
| :--- | ---: | ---: |
| $\mathbf{p}_{12}$ | 0.09 | 0.09 |
| $\mathbf{p}_{13}$ | 0.15 | 0.24 |
| $\mathbf{p}_{14}$ | 0.45 | 0.69 |
| $\mathbf{p}_{15}$ | 0.31 | 1 |

Figure 6: Decision making in ACO

In addition, each ant $k$ possesses a memory $M^{k}$. It stores the list of cities already visited in the relevant order. This serves as a basis to determine the feasible neighborhoods $N_{i}^{k}$. Furthermore, it enables the ant to compute the length $C^{k}$ of its tour $T^{k}$ as well as to follow the tour in the opposite way to deposit pheromones. The pheromone trail update includes on the one hand a phase of evaporation by a factor $\alpha$ and on the other an update of an edge $(i, j)$ by all ants $\sum_{k=1}^{m} \Delta \tau_{i j}^{k}(t)$.
$\tau_{i j}(t+1)=(1-\alpha) * \tau_{i j}(t)+\sum_{k=1}^{m} \Delta \tau_{i j}^{k}(t) \quad \forall(i, j)$

A single ant $k$ reinforces the edge with $\Delta \tau_{i j}^{k}=1 / C^{k}$, if edge $(i, j)$ belongs to $T^{k}$ and not at all otherwise. Consequently, the quality (shortness) of a tour and ant frequency on an edge increases its pheromone level.

Whether ants construct their solutions sequentially or in parallel doesn't influence the quality of algorithmic output significantly. AS did not turn out to
be competitive with other solution approaches to the TSP but the idea was adapted and modified.

### 3.1.4 Ant Colony System

When comparing ACS to AS, the main differences are based on exploration and exploitation. To start with, the construction phase uses a different, more aggressive state transition rule. Ant $k$ chooses vertex $j$ after vertex $i$ according to

$$
\begin{equation*}
j=\arg \max l \in N_{i}^{k}\left\{\tau_{i l}\left[\eta_{i l}\right] \beta\right\}, \quad \text { if } q \leq q_{o} \tag{3.4}
\end{equation*}
$$

$j=J$,
otherwise.
$q$ is a random variable uniformly distributed in $[0,1]$ and $q_{0}\left(0 \leq q_{0} \leq 1\right)$ is a parameter. If $q \leq q_{0}$, the move with the highest state transition value is performed. Otherwise the next step is assigned by $J . J$ is a random variable that is determined by the probabilistic state transition rule in (3.1) with $\zeta=1$ and the roulette wheel decision method. Exploitation of existing knowledge (memorized pheromone trails and heuristic information) and therefore concentration on the best-so-far tour occurs with probability $q_{0}$ while exploration of other tours is performed with probability $\left(1-q_{0}\right)$.

Another difference lies in the pheromone updating rule. In ACS, global and local updating procedures occur. Every ant performs local modification of the pheromone level immediately after traversing an edge. Hence, the updating process is partly executed during the tour construction phase for each edge. The local update rule is

$$
\begin{equation*}
\tau_{i j}=(1-\rho) \tau_{i j}+\rho \tau_{0} \tag{3.5}
\end{equation*}
$$

with parameters $\tau_{0}$ (initial pheromone value $1 / n C^{n n}$ ) and $0 \leq \rho \leq 1 . \rho$ regulates the amount of evaporation and pheromone deposit during the updating procedure. Local update has the effect that high frequency on an edge $(i, j)$
leads to decreasing pheromone level $\tau_{i j}$. Other ants are less likely to cross this edge which in turn favors the exploration of new edges and avoids stagnation. During global update, only the ant that constructed the best-so-far tour may add pheromone after each iteration:
$\tau_{i j}=(1-\alpha) \tau_{i j}+\alpha \Delta \tau_{i j}^{b s}, \quad \forall(i, j) \in T^{b s}$.

Naturally, now $\Delta \tau_{i j}^{b s}=1 / C^{b s}$ where $C^{b s}$ is the length of the best-so-far tour $T^{b s}$. Only edges on this tour are affected by pheromone deposit as well as evaporation.
So far, ACS implementations have shown that, using parallel construction by all ants does not exceed solution quality of sequential construction. Using the iteration best tour instead of the best-so-far tour in global updating leads to worse results solving larger TSP instances. For all further use of ACO, I will apply sequential construction and global updating according to the best-so-far tour.

### 3.1.5 Other ACO algorithms

## Elitist Ant System

The first update of AS was Elitist Ant System which uses stronger pheromone trail laying on the best-so-far tour $T^{b s}$ with length $C^{b s}$ constructed by an ant. In addition to the pheromone update applied in AS (equation (3.2)), edges belonging to $T^{b s}$ receive $e \Delta \tau_{i j}^{b s}$ additional pheromone. Parameter $e$ is a weight for $T^{b s}$ and $\Delta \tau_{i j}^{b s}$ equals $1 / C^{b s}$.

## Rank-Based Ant System

Rank-Based Ant System sorts ants according to the quality of their solutions constructed and only the $(w-1)$ best-ranked ants as well as the best-so-far ant (with rank $w$ ) may deposit pheromone weighted according to their rank:

$$
\begin{equation*}
\tau_{i j}(t+1)=(1-\rho) * \tau_{i j}(t)+\sum_{r=1}^{w-1}(w-r) \Delta \tau_{i j}^{r}(t)+w \Delta \tau_{i j}^{b s} \quad \forall(i, j) \tag{3.7}
\end{equation*}
$$

## MAX-MIN Ant System

In MAX-MIN Ant System, only the best ant (either the best-so-far or the iteration-best) lays pheromone trails. In order to prevent stagnation by following only one ant, limits $\left[\tau_{\text {min }}, \tau_{\max }\right]$ for the amount of deposit are introduced. First, the trails are initialized with $\tau_{\max }$ and evaporation is small. If signs of stagnation emerge after some time, trails are reset to $\tau_{\max }$.

### 3.2 GENIUS algorithm

GENIUS, a two phase heuristic composed of the GENI phase (abbr. for General Insertion) and the US phase (abbr. for Unstringing and Stringing), first constructs and then re-optimizes a tour [13].
This two-phase heuristic consists of an iterative insertion heuristic GENI and a post-optimization procedure US and was first applied to the TSP [13]. In the following sections, both heuristics will be described separately. When looking at a set of vertices that should belong to a tour, GENI iteratively includes them one by one until all vertices are visited. Afterwards, US improves the tour also vertex by vertex.

### 3.2.1 GENI

"Generalized insertion can be described as an insertion procedure which uses a limited form of incremental local search" [3].

The insertion procedure GENI adds a vertex $v$, currently not on the tour, between two vertices already belonging to the tour. Initially, these two vertices need not appear in consecutive order along the tour. However, after vertex $v$ was inserted into the tour, the two vertices will be the preceding and succeeding neighbor of $v$. This procedure combines local optimization and insertion steps.

In general, any vertex $v_{h}$ on any tour has a predecessor $v_{h-1}$ and a successor $v_{h+1}$. As stated above, vertex $v$ should be integrated in the tour between any two vertices $v_{i}$ and $v_{j}$.

In order to limit the search space for any vertex $v \in V$ waiting to be inserted, GENI checks a set of $p$ vertices already on the tour belonging to the p neighborhood $N_{p}(v)$, including only those vertices closest to vertex $v$ (based on the distance or travel time matrix $\left.C=\left(c_{i j}\right)\right)$. The parameter $p$ is usually set to a relative small number somewhere between 4 and 7. If a tour consists of less than $p$ vertices, all members of this tour belong to the neighborhood $N_{p}(v)$ of a vertex $v \in V$. GENI will investigate insertions for a given parameter p.

Gendreau et al. describe two different types of insertion possibilities [13].

### 3.2.1.1 Type I Insertion

Vertex $v_{k}$ lies on the path between $v_{j}$ and $v_{i}$ for a clockwise orientation of the tour. Vertices $v_{i}$ and $v_{j}$ must be chosen such that $v_{i}, v_{j} \in N_{p}(v)$ and vertex $v_{k}$ such that $v_{k} \in N_{p}\left(v_{i+1}\right)$. Also, $v_{k} \neq v_{i}$ and $v_{k} \neq v_{j}$ has to be taken into account.

Figure 7: Type I insertion procedure

Each move demands an insertion (limited to $N_{p}(v)$ ) and one 3-opt exchange. Figure 7 shows that after choosing vertices $v_{i}, v_{j}$ and $v_{k}$, inserting vertex $v$ leads to the replacement of old edges $\left(v_{i}, v_{i+1}\right),\left(v_{j}, v_{j+1}\right)$ and $\left(v_{k}, v_{k+1}\right)$ by new edges $\left(v_{i}, v\right),\left(v_{,}, v_{j}\right),\left(v_{i+1}, v_{k}\right)$ and $\left(v_{j+1}, v_{k+1}\right)$ in order to construct the best possible GENI tour. One of the latter four edges is constructed due to the insertion of $v$ and three are substitutes for the first three edges (3-opt local reoptimization). Furthermore, paths $\left(v_{i+1}, v_{j}\right)$ and $\left(v_{j+1}, v_{k}\right)$ are reversed. The objective of type I insertion procedure is to choose the best of all possible moves for $v_{i}, v_{j} \in N_{p}(v)$ and $v_{k} \in N_{p}\left(v_{i+1}\right)$.

### 3.2.1.2 Type II Insertion

Again, vertex $v_{k}$ lies on the path between $v_{j}$ and $v_{i}$. Furthermore, vertex $v_{l}$ is located on the path from $v_{i}$ to $v_{j}$ for a clockwise orientation of the tour. Vertices $v_{i}$ and $v_{j}$ must be chosen such that $v_{i}, v_{j} \in N_{p}(v)$, vertex $v_{k}$ such that $v_{k} \in N_{p}\left(v_{i+1}\right)$ and vertex $v_{l}$ such that $v_{l} \in N_{p}\left(v_{j+1}\right)$. Also, $v_{l} \neq v_{i}, v_{i+1}$ and $v_{k} \neq v_{j}, v_{j+1}$ has to be taken into account.

A type II insertion of vertex $v$ results in the deletion of old edges $\left(v_{i}, v_{i+1}\right),\left(v_{l-1}, v_{l}\right),\left(v_{j}, v_{j+1}\right)$ and $\left(v_{k}, v_{k-1}\right)$. The following figure shows that they are replaced by new edges $\left(v_{i}, v\right),\left(v, v_{j}\right),\left(v_{l}, v_{j+1}\right),\left(v_{k-1}, v_{l-1}\right)$ and $\left(v_{i+1}, v_{k}\right)$ to obtain the best possible GENI constructed tour. Paths $\left(v_{i+1}, v_{l-1}\right)$ and $\left(v_{l}, v_{j}\right)$ are inverted. The difference to type I is that the local search and re-optimization is achieved by running a 4-opt algorithm instead of a 3-opt.

Figure 8: Type II insertion procedure
Both types of insertion are considered likewise for a clockwise and a counterclockwise orientation of the tour which leads to four different types of insertions. Moreover, for each type of insertion, the potential number of choices for $v_{i}, v_{j}, v_{k}$ and $v_{l}$ is $n^{4}$, where $n$ is the number of vertices in total. The
introduction of neighborhoods to narrow the search space reduces the complexity to $O\left(p^{4}\right)$, where $O$ describes the effect of the problem size on the algorithm's usage of computational resources. If $v_{i} \in N_{p}(v)$, an examination of the insertion of $v \in V$ between two consecutive vertices $v_{i}$ and $v_{i+1}$ will also be executed. Finally, the best overall insertion will be executed.

### 3.2.1.3 GENI algorithm

The GENI algorithm passes through the following iterations:

## Iteration 1:

An initial tour is created by a random subset selection containing three vertices (one of them the depot $v_{0}$ ).

The p-neighborhoods for every vertex are initialized.

## Iteration 2:

Random selection of any vertex $v \in V$ not yet inserted in the tour. The least cost insertion of the chosen vertex $v \in V$ with respect to all possible insertions of type I and II is selected.

The p-neighborhoods of all remaining vertices are updated due to the insertion of vertex $v \in V$ on the tour.

## Iteration 3:

If all vertices have been inserted, END. Else go to iteration 2.

Inserting vertex $v \in V$ and updating the tour requires $O(n)$ time. As iteration 2 has to be executed $n-3$ times, the overall complexity for the GENI algorithm is $O\left(n p^{4}+n^{2}\right)$.

### 3.2.2 US

The post-optimization algorithm US [13] can be operated on tours produced by any algorithm. The main feature of $U S$ is to remove a vertex ( $U$ - unstring) from a feasible tour and reinsert ( S - string) it. While the stringing process is
identical with iteration 2 of the GENI algorithm, unstringing a given tour simply reverses the insertion procedure used by the GENI algorithm.
Again, there are two possible options of reconnecting the members of the tour after the removal of any vertex $v_{i}$.

### 3.2.2.1 Type I Unstringing

Vertices $v_{j}$ and $v_{k}$ are chosen such that $v_{j} \in N_{p}\left(v_{i+1}\right)$ and $v_{k} \in N_{p}\left(v_{i-1}\right)$ is a vertex on the path $\left(v_{i+1}, \ldots, v_{j-1}\right)$. Figure 9 demonstrates an US iteration:

Figure 9: Type I unstringing of vertex $v_{i}$ from the tour

The old edges $\left(v_{i-1}, v_{i}\right),\left(v_{i}, v_{i+1}\right),\left(v_{k}, v_{k+1}\right)$ and $\left(v_{j}, v_{j+1}\right)$ are removed and replaced by edges $\left(v_{i-1}, v_{k}\right),\left(v_{i+1}, v_{j}\right)$ and $\left(v_{k+1}, v_{j+1}\right)$. Additionally, paths $\left(v_{i+1}, v_{k}\right)$ and $\left(v_{k+1}, v_{j+1}\right)$ are reversed.

### 3.2.2.2 Type II Unstringing

As before, vertices $v_{j}$ and $v_{k}$ are chosen such that $v_{j} \in N_{p}\left(v_{i+1}\right)$ and $v_{k} \in N_{p}\left(v_{i-1}\right)$ is a vertex on the path $\left(v_{i+1}, \ldots ., v_{j-1}\right)$. Additionally, vertex $v_{l}$ is selected so that $v_{l} \in N p\left(v_{k+1}\right)$ on the path $\left(v_{j}, \ldots, v_{l+1}\right)$. Figure 10 demonstrates an US iteration:

Figure 10: Type II unstringing of vertex $v_{i}$ from the tour

Then, old edges $\left(v_{i-1}, v_{i}\right),\left(v_{i}, v_{i+1}\right),\left(v_{j-1}, v_{j}\right),\left(v_{l}, v_{l+1}\right)$ and $\left(v_{k}, v_{k+1}\right)$ are removed and replaced by $\left(v_{i-1}, v_{k}\right),\left(v_{i+1}, v_{j-1}\right),\left(v_{i+1}, v_{j}\right)$ and $\left(v_{l}, v_{k+1}\right)$. Again, two paths, $\left(v_{i+1}, v_{j-1}\right)$ and $\left(v_{l+1}, v_{k}\right)$, are inverted.

### 3.2.2.3 Stringing

Stringing works just like a GENI insertion but now different neighborhood structures possibly lead to new re-insertion positions and therefore to a changed vertex sequence.

### 3.2.2.4 US algorithm

The following iterations demonstrate the work flow of the US algorithm:

## Iteration 1:

Use an initial tour $H$ of cost $z$ created by any algorithm.
Set the best-so-far tour $H^{*}:=H$ and the best-so-far cost of the tour $z^{*}:=z$ and $t:=1$;

## Iteration 2:

Randomly select a vertex $v_{i}$ that has not been considered yet. First, unstring and string using both types and possible tour orientations for vertex $v_{i}$ of the current tour.

The resulting tour $H^{\prime}$ has cost $z^{\prime}$.

- If $z^{\prime}<z^{*}$, set $H^{*}:=H^{\prime}, z^{*}:=z^{\prime}$ and $t:=1$; repeat Iteration 2;
- If $z^{\prime} \geq z^{*}$, set $t:=t+1$;repeat Iteration 2 ;
- If $t=n+1$, STOP. The best available tour is $H^{*}$ with costs $z^{*}$.

### 3.3 PRIMAL1 set covering heuristic

The PRIMAL1 set covering heuristic [2] was developed to solve SCPs.
In order to keep track of what is supposed to happen during solving the CTP, I will adapt the formulations used in the SCP model of section 2.4.2 to the ones used in the CTP model in 2.2 in the next section.

PRIMAL1 first sets $y_{k}:=1$ for all $v_{k} \in T$ and then iteratively adds the remaining vertices (columns) $v_{k}$ following a greedy criterion that minimizes the function $f\left(c_{k}, b_{k}\right)$. For each individual vertex (column) $v_{k}$ with $y_{k}=0$, the parameter $b_{k}$ sums up uncovered vertices (rows) $v_{\ell} \in W$ (the set that has to be covered) with a binary coefficient $\delta_{\ell k}=1$. This means that all vertices (rows) $v_{\ell} \in W$ covered by a vertex (column) $v_{k} \in V \backslash S$ but not by the temporary solution are added up to $b_{k}$. Three different versions of the function $f\left(c_{k}, b_{k}\right)$ are considered and applied to the set covering problem:

$$
\begin{align*}
& f\left(c_{k}, b_{k}\right)=c_{k} / \log _{2} b_{k}  \tag{i}\\
& f\left(c_{k}, b_{k}\right)=c_{k} / b_{k},  \tag{ii}\\
& f\left(c_{k}, b_{k}\right)=c_{k} . \tag{iii}
\end{align*}
$$

Vertices (columns) $v_{k} \in V$ are sorted according to the version of the function $f\left(c_{k}, b_{k}\right)$ currently in use and the cheapest insertion is performed. At the beginning, criterion (i) is applied until all rows $v_{\ell} \in W$ are covered. If at least one vertex (row) $v_{\ell} \in W$ with $\delta_{\ell k}=1$ is covered by more than one vertex (column) $v_{k} \in V$, the associated vertices (columns) that overcover the row are deleted from the partial solution and sorted again, now according to criterion (ii). Once more, overcovering vertices (columns) are removed, criterion (iii) is applied and the final solution of the first run is obtained.
The heuristic is run a second time with criteria sequence (i), (iii) and (ii). The best sequence from both runs is kept.

### 3.4 Solving the CTP

After an introduction of the CTP, of the components it can be separated into and of possible solution techniques for these components, this section focuses on solving the problem itself. I combine solution methods for the TSP and the SCP in order to find a good solution for the CTP. The first attempt is the same heuristic approach as applied by Gendreau et al. [14] which uses GENIUS and PRIMAL1.

The second attempt applies ACO with GACS for the TSP and SCACS for the SCP. I named the combination of these two methods ACS for the CTP (CTACS). The algorithms created are described below.

### 3.4.1 $\quad \mathrm{H}$-1-CTP heuristic

The combination of PRIMAL1 and GENIUS results in the approximate algorithm $\mathrm{H}-1-\mathrm{CTP}$ [16]. It passes through the following iterations twice, considering the same covering criteria sequence as in PRIMAL1. $H$ is the set of vertices belonging to the current TSP tour under construction, $z$ the cost of this tour,
$H^{*}$ the local optimum tour, $z^{*}$ its cost and $f\left(c_{k}, b_{k}\right)$ the current covering criterion.

## Iteration 1 - Initialization

Set $H:=T$ and $z^{*}:=\infty, f\left(c_{k}, b_{k}\right)=(i)$ (PRIMAL1);

## Iteration 2 - Construction

Using GENIUS, construct a Hamiltonian cycle over $H$ where $z$ represents the length of the tour;

## Iteration 3 - Termination

If one vertex $v_{\ell} \in W$ is not yet covered by the tour over $H$, go to iteration 4.
Else, if $z \leq z^{*}$, set $z^{*}:=z$ and $H^{*}:=H$.
If the covering criterion (PRIMAL1) is the last one, the local optimum is given by $H^{*}$ with cost $z^{*}$.
Else remove all vertices from $H$ associated with over-covered vertices of $W$ and move to the next covering criterion (PRIMAL1).

## Iteration 4 - Selection

A coefficient $c_{k}$ representing the cheapest insertion of $v_{k}$ in the current tour $H$ is calculated for every $v_{k} \in V \backslash H$. The best vertex $v_{k}$ with respect to the current covering criterion is inserted into $H$ (PRIMAL1).
Set $H:=H \cup\left\{v_{k}\right\}$ and go to iteration 2.

The better of the two runs then delivers the final solution of the CTP.

### 3.4.2 ACS for the CTP

The metaheuristic approach CTACS uses the idea of the COVTOUR Covering Salesman Problem heuristic [7] where the SCP was solved first and this solution was then used to formulate the TSP instance which was then solved separately. Here, I use ACS to solve the SCP and then GACS to solve the resulting TSP problem. The following sections introduce the two solution approaches in detail.

### 3.4.2.1 GACS

The classical ACS algorithm uses a nearest neighbor approach to choose the next city to be visited. The next vertex to be inserted is selected according to the probabilistic state transition rule which incorporates the pheromone trails and the heuristic information. Also, the vertex will always be positioned at the end of a tour under construction. Without the degree of probability, ACS would deliver identical vertex sequences and therefore equal results for the same starting point. Consequently, solutions generated by the classical ACS strongly depend on the selection order of the cities. GACS introduces the GENI heuristic. Here, the next vertex to be inserted is chosen in a random fashion. However, now the insertion procedure is more accurate because the position of the vertex on the tour is chosen very carefully and is more important than the assigned vertex.

Two adjustments concerning the cost of an edge and the state transition rule have to be made.
First, the cost of an edge $(i, j)$ now depends on its length $c_{i j}$ as well as on the amount of pheromone $\tau_{i j}$ stored on it.

The modified cost of an edge is:
$c^{\prime}{ }_{i j}=\frac{c_{i j}}{1+\gamma \cdot \tau_{i j}^{R}} \quad \forall(i, j) \in E$
with the relative amount of pheromone $\tau_{i j}^{R}$ :
$\tau_{i j}^{R}=\frac{\tau_{i j}}{\max _{(k, l \in E}\left(\tau_{k l}\right)}$.

The original cost $c_{i j}$ of edge $(i, j)$ is taken from the distance or travel time matrix $C=\left(c_{i j}\right) . \tau_{i j}^{R}$ is the relative amount of pheromone on edge $(i, j)$ where the original pheromone value $\tau_{i j}$ is normalized between 0 and 1 on every edge. If $\max _{(k, l) \in E}\left(\tau_{k l}\right)=0$, which is the case when no pheromone has been distributed on the edges, $\tau_{i j}^{R}=0$ for every edge. Parameter $\gamma$ modifies the relative influence of pheromone values on an edge. Equation (3.7) assigns fewer costs to edges with higher pheromone values. In addition, it provides a lower and
upper bound on the adjusted edge costs $c_{i j}^{\prime}$. On the one hand it can not exceed the original cost $c_{i j}$ and on the other it never declines to less than half of them. Second, the state transition rule has to be modified with respect to the GENI insertion method. As already mentioned, without probabilistic decision making, the classical ACS would produce identical selection orders for the same starting point, which in turn results in equivalent solutions. GACS may use different selection orders that still result in the same solutions. Consequently, GACS uses a new probabilistic state transition rule with a rank-based approach to alter the search space and to decide on the GENI insertion type used for the next city. In every iteration, the available moves consisting of all possible GENI insertions are reduced to a parameter $S^{G E N I}$ in order to prevent bad choices. They are then ranked from the cheapest insertion with rank $S^{G E N I}$ to the most expensive insertion with rank 1. An insertion with rank $t$ will then be selected between 1 and $S^{G E N I}$ according to the following state transition rule:

$$
t=\left\{\begin{array}{lc}
S^{G E N I}, & \text { if } q \leq q_{0}  \tag{3.9}\\
T^{G E N I}, & \text { otherwise } .
\end{array}\right.
$$

As in (3.4), $q$ is a random variable uniformly distributed in $[0,1]$ and parameter $q_{0}$ is $\left(0 \leq q_{0} \leq 1\right) . T^{G E N I}$ is a random variable with the following probability distribution:

$$
\begin{equation*}
p\left(T^{G E N I}=t\right)=\frac{t}{\sum_{t^{\prime}=1}^{S^{G E N I}} t^{\prime}}=\frac{2 t}{S(S+1)}, \quad t=1, \ldots ., S^{G E N I} . \tag{3.10}
\end{equation*}
$$

In this case, the roulette wheel decision process between ranks $1, \ldots, S^{G E N I}$ appoints the next insertion.
The ranking system allows better distinctions between almost equal moves and prevents stagnation by setting the selection probability of the best insertion below 1. According to these two equations, the cheapest insertion with rank $t=S^{G E N I}$ will be chosen with the highest and the most expensive insertion with rank $t=1$ with the lowest probability. I have settled for $S^{G E N I}=5$, just like Le Louran et al. [19], in order to limit the search space and to prevent too intense diversification.

The GACS algorithm can be summarized in the following way:

Initialization of pheromones and parameters
For I iterations do:
For ant 1 to $m_{a}$ do:
GENI algorithm
Local pheromone update;
Global pheromone update;
GACS best solution output;
Figure 11: GACS algorithm

### 3.4.2.2 SCACS

In general, ACO for the SCP assigns column $j$ a pheromone value $\tau_{j}$ and a heuristic value $\eta_{j}$ where $\tau_{j}$ represents the learned desirability and $\eta_{j}$ the heuristic desirability of choosing column $j$. A single ant starts with an empty memory $M^{k}$ and constructs a solution by probabilistically adding columns step by step until all rows are covered. Again, the probabilistic rule of column choice depends on the pheromone value $\tau_{j}$ and the heuristic value $\eta_{j}$. After all ants have constructed their solution, local search may be implemented and finally the pheromone trails are updated.
However, three main differences to other ACO applications such as the TSP appear when solving the SCP: ants do not need the same number of iterations to solve the problem, the order of including columns has no influence on the solution and possible redundant information in intermediate solutions may be eliminated by local search before updating.

For the solution of the SCP embedded in the CTP, I will use the ACS algorithm introduced by Lessing et al. [20] that more or less represents the ACS framework introduced in 3.1.2. The state transition rule for choosing the next column in the SCP is:

$$
j=\left\{\begin{array}{cc}
\arg \max _{l \notin S_{k}}\left\{\tau_{l}\left[\eta_{l}\right]^{\beta}\right\}, & \text { if } q \leq q_{0},  \tag{3.11}\\
\operatorname{draw}(J), & \text { otherwise } .
\end{array}\right.
$$

Again, $q$ is a random variable uniformly distributed in $[0,1], q_{0}\left(0 \leq q_{0} \leq 1\right)$ is a parameter, $S_{k}$ is the partial solution obtained by ant $k$ and $\operatorname{draw}(J)$ is a random variable that equals the probabilistic state transition rule. $\beta$ determines the influence of the heuristic information $\eta$ on the decision. The corresponding probability $p_{j}^{k}$ of ant $k$ choosing column $j$ equals:

$$
\begin{equation*}
p_{j}^{k}=\frac{\tau_{j}\left[\eta_{j}\right]^{\beta}}{\sum_{h \notin S_{k}} \tau_{h}\left[\eta_{h}\right]^{\beta}}, \quad \text { if } j \notin S_{k} \tag{3.12}
\end{equation*}
$$

If $q \geq q_{0}$, the next column will be chosen through roulette wheel just as in AS, ACS and GACS. Of course, if $j \in S_{k}$ then $p_{j}^{k}=0$. In addition, redundant columns have to be deleted to ensure good solution quality.

Ant $k$ proceeds with the local pheromone update in order to increase exploration after it has added a column $j$ to its partial solution $S_{k}$ according to

$$
\begin{equation*}
\tau_{j}=(1-\rho) \tau_{j}+\rho \tau_{0} \tag{3.13}
\end{equation*}
$$

with parameters $\tau_{0}=1 /\left(n \cdot z_{G R}\right)$ where $z_{G R}$ is the cost of a greedy solution and $0 \leq \rho \leq 1$.

Finally, when the construction process of each ant has ended, the best-so-far ant updates the pheromone trails globally by

$$
\begin{equation*}
\tau_{j}=(1-\alpha) \tau_{j}+\alpha \cdot \Delta \tau_{j}^{b s}, \quad \forall j \in S^{b s} \tag{3.14}
\end{equation*}
$$

with the best-so-far solution $S^{b s}$, its cost $z^{b s}$ and $\Delta \tau_{j}^{b s}=1 / z^{b s}$.
Another important factor of SCACS is to decide on the best kind of heuristic information to use for the state transition. Lessing et al. [20] list seven different types of possible heuristic information which they categorize as static
and dynamic. I will focus on three approaches, namely column cost, cover cost and Marchiori and Steenbeek cover costs [21].

## Column costs

This approach, using static costs, is very straight forward because the heuristic information $\eta_{j}$ is defined as the column cost reciprocal $1 / c_{j}$.

## Cover costs

When looking back at the PRIMAL1 algorithm (3.3), the parameter $b_{k}$ was the number of rows covered by vertex $k$ but not by a partial solution. With cover costs, the heuristic information $\eta_{j}$ equals $b_{j} / c_{j}$ for all columns not yet part of the solution. Subscript $k$ is replaced by $j$.

## Marchiori and Steenbeek (M\&S) cover costs

This is a variant of the cover costs above. $\operatorname{cov}(S)$ is the set of rows covered by the columns of a partial solution $S$. The set of rows covered by column $j$ but not by any other column in $S$ is $\operatorname{cov}(j, S)$. The minimum cost $c_{\text {min }}(i)$ of all columns covering row $i$ not yet part of the solution and member of $\operatorname{cov}(j, S)$ must be determined. In order to derive the cover value $c v(j, S)$ (of a column $j$ with respect to a partial solution $S$ ), $c_{\text {min }}(i)$ for all rows of $\operatorname{cov}(j, S)$ have to be summed up:

$$
\begin{equation*}
c v(j, S)=\sum_{i \in \operatorname{cov}(j, S)} c_{\min }{ }^{(i)} \tag{3.15}
\end{equation*}
$$

The modified cover costs cov_val( $j, S$ ) are:

$$
\operatorname{cov}_{-} \operatorname{val}(j, S)=\left\{\begin{array}{cl}
\infty, & \text { if } c v(j, S)=0,  \tag{3.16}\\
c_{j} / c v(j, S), & \text { otherwise } .
\end{array}\right.
$$

The heuristic information $\eta_{j}$ equals the (M\&S) cover costs $1 / \operatorname{cov}_{-} \operatorname{val}(j, S)$.

Three of the remaining four methods used in [20] apply normalized Lagrangean costs instead of column costs $c_{j}$ in the above variants and the last one uses lower bounds. However, I decided not to include a Lagrangean approach to keep the scope of this thesis manageable.
The SCACS algorithm can be summarized as:

Initialization of pheromones and parameters
For I iterations do:
For ant 1 to $m_{a}$ do:
Construct solution;
Eliminate redundant columns;
Local update;
Global pheromone update;
SCACS best solution output;
Figure 12: SCACS algorithm

### 3.4.2.3 CTACS

I combined the two algorithms described above to construct CTACS and to solve the CTP. The set $V$ accounts for the columns and the set $W$ for the rows in the SCP. First, a tour is constructed with GENI over all vertices within the set $T \in V$. The column cost for every vertex of set $V \backslash T$ is determined by calculating the cost of a GENI insertion in the tour over $T$ for every vertex. The column coverage naturally depends on the choice of the covering distance $c$. To find an initial pheromone level for SCACS, a greedy solution is created and then SCACS is run. Then I use the vertices obtained by SCACS to generate a GENI solution to derive the initial pheromone level for GACS. GACS then constructs the final CTP solution over the vertices obtained from SCACS.

## 4 Computational results

All algorithms described above - GENI, GENIUS, PRIMAL1, H-1-CTP, GACS, SCACS and CTACS - where implemented in C++ programming language. First, the influence of neighborhood size on GENI and GENIUS results was tested. Then GACS performance with different parameter values was observed. Furthermore, GENIUS, a multi-start GENI heuristic (mGENI) and GACS were compared while running on TSP instances. Parameter sensitivity of the SCACS was tested on a set of SCPs taken from the ORLIB [4]. I also tested the impact of the different types of heuristic information on solution quality. The algorithm was then compared to PRIMAL1.

Finally, $\mathrm{H}-1$-CTP and CTACS where run on various stochastic CTPs and compared to each other.

### 4.1 Tests on the TSP part of the problem

### 4.1.1 Neighborhood size for GENI and GENIUS

In order to observe the influence of neighborhood size on the performance of GENI and GENIUS on TSP instances, the algorithms where tested on a set of four different problems. The Euclidean problems Berlin52, st70 and pr107 with 52, 70 and 107 vertices where taken from the TSPLIB library [23] and downloaded from [24]. In addition, KubLE25 with 25 vertices with $x$ and $y$ coordinates randomly distributed between 0 and 100 was generated to test how the algorithms react to different problem sizes. The neighborhood size range was set between $p=3$ and $p=9$. For each size and problem, the algorithms where run ten times. The average cost of a tour generated by GENI and GENIUS are shown in tables 1 and 2 . The best result for each data set is highlighted with bold font.

|  | $\mathbf{p}$ |  |  |  |  |  |  |  |

| pr107 | 48721.34 | 46128.57 | 45568.39 | 45278.60 | 45163.04 | 45099.95 | 45024.90 |

Table 2: Importance of neighborhood size for GENIUS

These results indicate that a larger search space leads to better solution quality up to a certain neighborhood size. It seems that increasing neighborhood size to excessively large neighborhoods (e.g., $p>7$ ) only has marginal benefit. From a neighborhood size of $p=7$ onwards, there was a significantly higher increase in computation time than for smaller neighborhood sizes. Consequently, I settled for $p=7$ for all the following algorithms including the GENI heuristic, which is also consistent with literature (e.g.: Gendreau et al. [13], Le Louran et al. [19]). The trade-off between resource cost and solution quality seems best with $p=7$.

### 4.1.2 Parameter analysis for GACS

The impact of parameters of GACS on TSP instances was tested on the same set of problems. Just like Le Louran et al. [19], I took the average cost of 10 different runs for each problem to show the solution quality of each parameter value. I set the number of iterations $I$ for each problem equal to the problem size (number of vertices) and the number of ants to $m_{a}=10$. Parameters were tested one at a time and the others where fixed to the values $\rho=0.5, \alpha=0.5$, $\gamma=0.5$ and $q_{0}=0.95$. I also chose to set the initial pheromone level $\tau_{0}=1 / C^{G E N I}$, where $C^{G E N I}$ is the cost of the tour acquired by one GENI run. As mentioned above, $p=7$.

The results for parameter $\rho$ - responsible for regulating the removal of pheromone from edges involved in the current tour during the local update (see equation (3.5)) - can be found in table 3. The lowest average costs over ten runs where obtained with values of $\rho \geq 0.75$ just as in the original article [19]. This implies that more search diversification leads to better solutions. Therefore, I set $\rho=0.75$.

|  | $\boldsymbol{\rho}$ |  |  |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: | ---: | ---: |
|  | Problem | $\mathbf{0}$ | $\mathbf{0 . 1}$ | $\mathbf{0 . 2 5}$ | $\mathbf{0 . 5}$ | $\mathbf{0 . 7 5}$ | $\mathbf{0 . 9}$ |
| KubLE25 | $\mathbf{3 9 5 . 6 4}$ | $\mathbf{3 9 5 . 6 4}$ | $\mathbf{3 9 5 . 6 4}$ | $\mathbf{3 9 5 . 6 4}$ | $\mathbf{3 9 5 . 6 4}$ | $\mathbf{3 9 5 . 6 4}$ | $\mathbf{1}$ |
| Berlin52 | 7561.66 | 7550.02 | 7551.98 | 7547.80 | 7546.40 | $\mathbf{7 5 4 4 . 4 3}$ | 7554.65 |
| St70 | 678.32 | 693.29 | 678.29 | 678.35 | $\mathbf{6 7 7 7 . 3 2}$ | 678.69 | 679.64 |
| pr107 | 44727.77 | 44482.26 | 44516.17 | $\mathbf{4 4 4 2 5 . 8 7}$ | 44474.28 | 44473.74 | 44477.48 |

Table 3: Influence of parameter $\rho$ on GACS solution quality

Table 4 shows that parameter $\alpha$ - used to control the amount of pheromone deposited on edges of the best-so-far tour during global update - provides the best solutions when set to $\alpha=0.25$. Consequently, the search does not focus too intensively on a certain solution that may only be a local optimum. This rather low value of $\alpha$ stimulates further search diversification.

|  | $\boldsymbol{\alpha}$ |  |  |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Problem | $\mathbf{0}$ | $\mathbf{0 . 1}$ | $\mathbf{0 . 2 5}$ | $\mathbf{0 . 5}$ | $\mathbf{0 . 7 5}$ | $\mathbf{0 . 9}$ |

| pr107 | 44613.28 | 44656.33 | 44483.13 | $\mathbf{4 4 4 2 5 . 8 7}$ | 44527.71 | 44528.90 | 45172.80 |

Table 4: Influence of parameter $\alpha$ on GACS solution quality

Parameter $\gamma$ coordinates the importance of pheromone in the evaluation of edge costs. Table 5 illustrates that GACS with $\gamma=0.5$ produces the best solutions and confirms the positive influence of pheromone trails on solution quality.

|  | $\gamma$ |  |  |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| Kroblem | $\mathbf{0}$ | $\mathbf{3 9 5 . 6 4}$ | $\mathbf{3 9 5 . 6 4}$ | $\mathbf{3 9 5 . 6 4}$ | $\mathbf{3 9 5 . 6 4}$ | $\mathbf{3 9 5 . 6 4}$ | $\mathbf{3 9 5 . 6 4}$ |
| Berlin52 | 7557.16 | 7559.91 | $\mathbf{7 5 4 7 . 8 0}$ | 7551.01 | 7557.99 | 7555.04 |  |
| St70 | 678.48 | $\mathbf{6 7 7 . 3 0}$ | 678.35 | 678.63 | 677.51 | 680.53 |  |
| pr107 | 44426.96 | 44471.70 | $\mathbf{4 4 4 2 5 . 8 7}$ | 44467.34 | 44481.94 | 44595.87 |  |

Table 5: Influence of parameter $\gamma$ on GACS solution quality

Solutions for different settings of $q_{0}$ can be found in table 6. It is remarkable that $q_{0}=1$ - the best GENI insertion is always performed - does not necessarily lead to the highest solution quality. Deviation from the best insertion provides better results which is why I settled for $q_{0}=0.98$.

|  | $q_{0}$ |  |  |  |
| :--- | :---: | :---: | :---: | :---: |
| Problem | $\mathbf{0 . 9}$ | $\mathbf{0 . 9 5}$ | $\mathbf{0 . 9 8}$ | $\mathbf{1}$ |

Table 6: Influence of parameter $q_{0}$ on GACS solution quality

After identifying the parameter settings as $q_{0}=0.98, \gamma=0.5, \alpha=0.25$ and $\rho=0.75$, I re-ran the problems to obtain results shown in table 7 . In 2 instances, I found better solutions than in all the proceeding tests by combining the optimal settings for all parameters. In the other 2 instances, the solution was equal to the best solution already obtained in the earlier tests.

| Problem | Solution |
| :--- | ---: |
| KubLE25 | 395.64 |
| Berlin52 | 7544.37 |
| St70 | 677.11 |
| pr107 | 44337.40 |

Table 7: GACS results with best parameters

A detailed summary of the test runs on each parameter can be found in appendix A .

### 4.1.3 GENI variants comparison

GENIUS, mGENI and GACS where tested on Euclidean problems from the TSPLIB with less than 300 vertices ( $n \leq 300$ ). mGENI runs through the GENI algorithm $m$ times without using already obtained results during further solution finding. For problems of a size up to 100 vertices, each algorithm was given the time needed to run $2.5 n$ GENI iterations. GACS and mGENI both produced quite similar results while GENIUS lagged behind in most problems. Table 8 shows this comparison between GACS, mGENI and GENIUS, where column "Opt." holds the best known solution from the TSPLIB, column "Total runtime" is the time needed for $2.5 n$ GENI iterations (in seconds), column "Gap" presents the percentage gap to "Opt." and column "Time" shows the runtime (in seconds) in which the different algorithms reached their best solution.

| Problem | Opt. | GACS | Time | Gap | mGENI | Time | Gap | GENIUS | Time | Gap | Runtime |

Table 8: Comparison of GACS, mGENI and GENIUS

Therefore, I ran only GACS and mGENI on larger instances. The next table indicates the positive influence of pheromones on the solution quality of most of the problems, as GACS beats mGENI in 8 out of 10 problems. This time, problems up to a size of 150 were given 3 hours runtime and larger ones 4 hours.

| Problem | Opt. | GACS | Time | Gap | mGENI | Time | Gap | Runtime |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

Table 9: Comparison of GACS and mGENI

These results suggest that, with increasing problem size, the importance of using pheromones grows and GACS delivers better solution quality than mGENI and GENIUS. However, pheromones occupy a lot of resources and GACS therefore takes longer to produce its best solution.

### 4.2 Tests on the SCP part of the problem

### 4.2.1 Parameter analysis for SCACS

I tested the parameters' sensitivity of SCACS algorithm on a set of 4 problems from the ORLIB. Problems SCP41, SCP43, and SCP44 are problems with $j=1000$ columns and $i=200$ rows. SCP57 consists of $j=2000$ columns and $i=200$ rows. Just as in my analysis of GACS, I averaged the costs of 10 different runs for every problem to show the impact of each parameter setting. The heuristic information chosen for these tests is cover costs because I first wanted to determine the ideal ACS parameters before examining heuristic information. The number of iterations $I$ for each problem equaled the number of rows. I used $m_{a}=5$ ants. While one parameters was tested, the others were kept constant at $\rho=0.1, \alpha=0.1, \beta=1$ and $q_{0}=0.9$. The initial pheromone level was set to $\tau_{0}=1 / z_{G R}$, where $z_{G R}$ is the cost found by a greedy solution.

Table 10 shows that the influence of the heuristic information $\eta_{j}$ on the choice of the next column to be included in the solution is of great importance. In accordance, I set $\beta$ to 5 for further testing.

|  | $\beta$ |  |  |
| :--- | :---: | :---: | :---: |
|  | $\mathbf{1}$ | $\mathbf{3}$ | $\mathbf{5}$ |
| SCP41 | 570.9 | 491.7 | $\mathbf{4 6 6 . 1}$ |
| SCP43 | 732.4 | 613.4 | $\mathbf{5 9 0 . 1}$ |
| SCP44 | 620.5 | 574.5 | $\mathbf{5 5 7 . 4}$ |
| SCP57 | 589.6 | 509.6 | $\mathbf{4 9 8 . 3}$ |

Table 10: Influence of parameter $\beta$ on SCACS solution quality
Although solutions in table 11 show that, with $q_{0}=0.99$, the algorithm performs best, I fixed $q_{0}$ to 0.98 . This ensures that a certain amount of diversification is created. Also, the gap between values with $q_{0}=0.99$ and $q_{0}=0.98$ was - with the exception of SCP57 - not very large.

|  | $q_{0}$ |  |  |  |
| :--- | :---: | :---: | :---: | ---: |
|  | $\mathbf{0 . 9}$ | $\mathbf{0 . 9 5}$ | $\mathbf{0 . 9 8}$ | $\mathbf{0 . 9 9}$ |
| SCP41 | 570.9 | 506.3 | $\mathbf{4 6 2 . 9}$ | 467 |
| SCP43 | 732.4 | 672.9 | 592 | $\mathbf{5 9 0}$ |
| SCP44 | 620.5 | 602.8 | 556.9 | $\mathbf{5 5 2 2 . 9}$ |
| SCP57 | 589.6 | 371.9 | 351.7 | $\mathbf{3 3 2 . 9}$ |

Table 11: Influence of parameter $q_{0}$ on SCACS solution quality

Results for the parameters for local and global pheromone update, $\rho$ and $\alpha$, in tables 12 and 13 suggest that the SCACS algorithm tends to associate those columns which produce good solution quality with high pheromone levels from the beginning. In order for the algorithm to perform well, these columns should be kept attractive for the further construction process. $\rho$ and $\alpha$ limit the level of evaporation. Therefore, I set $\rho=0.1$ and $\alpha=0.2$.

|  | $\rho$ |  |  |
| :--- | :---: | :---: | :---: |
| Problem | $\mathbf{0 . 1}$ | $\mathbf{0 . 2}$ | $\mathbf{0 . 3}$ |
| SCP41 | $\mathbf{5 7 0 . 9}$ | 613.1 | 682.9 |
| SCP43 | $\mathbf{7 3 2 . 4}$ | 785.3 | 830.2 |
| SCP44 | $\mathbf{6 2 0 . 5}$ | 698.5 | 753 |
| SCP57 | $\mathbf{5 8 9 . 6}$ | 649.5 | 672.1 |

Table 12: Influence of parameter $\rho$ on SCACS solution quality

|  | $\alpha$ |  |  |
| :--- | :---: | :---: | :---: |
|  | $\mathbf{0 . 1}$ | $\mathbf{0 . 2}$ | $\mathbf{0 . 3}$ |
| SCP41 | 570.9 | $\mathbf{5 0 4 . 2}$ | 534 |
| SCP43 | 732.4 | $\mathbf{6 9 4 . 1}$ | 730.1 |
| SCP44 | $\mathbf{6 2 0 . 5}$ | 629.8 | 623.2 |
| SCP57 | 589.6 | $\mathbf{5 3 9 . 1}$ | 543 |

Table 13: Influence of parameter $\alpha$ on SCACS solution quality

Consequently, the best parameter settings are: $\rho=0.1, \alpha=0.2, \beta=5$ and $q_{0}=0.98$. I used them in all further applications of SCACS.

### 4.2.2 Heuristic information in SCACS

After determining the best parameter settings, I compared the three types of heuristic information - column cost, cover costs and M\&S cover costs. I ran SCACS only three times for each information type because a strong trend towards M\&S cover costs developed immediately. They outperformed column costs and cover costs by far (table 14).

| Problem | Column Cost | Cover Cost | M\&S Cover Cost |
| :--- | :---: | :---: | :---: |
| SCP41 | 1758.67 | 450.00 | $\mathbf{4 3 4 . 6 7}$ |
| SCP43 | 3214 | 575.67 | $\mathbf{5 4 3 . 3 3}$ |
| SCP44 | 2818.67 | 529.67 | $\mathbf{5 0 1}$ |
| SCP57 | 1340.33 | 318.33 | $\mathbf{3 0 8 . 6 7}$ |

Table 14: SCACS tests on heuristic information

### 4.2.3 PRIMAL1 vs. SCACS

PRIMAL1 was tested on the four problems used before to determine the optimal parameter settings and heuristic information as well as on some additional problems. In the following table the values are compared to those produced by SCACS and to optimal solutions. Column "Opt." holds the best known solution from the ORLIB, column "Gap" presents the percentage gap to "Opt." and column "Time" shows the runtime (in seconds) in which the different algorithms reached their best solution.

| Problem | Opt. | SCACS | Gap | Time | PRIMAL1 | Gap | Time |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| SCP41 | 429 | $\mathbf{4 3 2}$ | $0.70 \%$ | 310 | 466 | $8.62 \%$ | 15 |
| SCP42 | 512 | $\mathbf{5 3 5}$ | $4.49 \%$ | 1703 | 556 | $8.59 \%$ | 15 |
| SCP43 | 516 | $\mathbf{5 4 1}$ | $4.84 \%$ | 401 | 561 | $8.72 \%$ | 15 |
| SCP44 | 494 | $\mathbf{4 9 5}$ | $0.20 \%$ | 482 | 538 | $8.91 \%$ | 15 |
| SCP45 | 512 | $\mathbf{5 1 6}$ | $0.78 \%$ | 2829 | 542 | $5.86 \%$ | 15 |
| SCP48 | 492 | $\mathbf{5 4 2}$ | $10.16 \%$ | 1771 | 556 | $13.01 \%$ | 15 |
| SCP52 | 302 | $\mathbf{3 1 4}$ | $3.97 \%$ | 3000 | 335 | $10.93 \%$ | 29 |
| SCP54 | 242 | $\mathbf{2 4 7}$ | $2.07 \%$ | 1230 | 249 | $2.89 \%$ | 30 |
| SCP56 | 213 | $\mathbf{2 2 1}$ | $3.76 \%$ | 1798 | 245 | $15.02 \%$ | 49 |
| SCP57 | 293 | $\mathbf{3 0 4}$ | $3.75 \%$ | 25 | 316 | $7.85 \%$ | 30 |

Table 15: PRIMAL1 vs. SCACS

The results show a clear dominance of SCACS. However, this appears to be quite obvious as PRIMAL1 only runs through the problem six times. Nevertheless, SCACS delivers solutions with significantly higher quality. The gap between SCACS results and the optimum is acceptable in most cases but could be improved (for example with local search) while solution quality of PRIMAL1 is rather poor.

### 4.3 Tests on the CTP

Unfortunately, unlike the TSP and the SCP, no test problems for the CTP exist. Therefore, I randomly created 5 problem instances with $V \subset W=\{1000\}$ CTP1k1 to CTP1k5 - and 5 with $V \subset W=\{2000\}$ - CTP2k1 to CTP2k5. The smaller problems were tackled in the following fashion: the size of $T$ was set to 3,5 and 10 and the size of $V$ to $0.1,0.15$ and 0.2 times $V \subset W=\{2000\}$ and $W=(V \subset W)-(T+V) \quad$ (e.g.: for $T=\{3\}, 3$ instances were run with $V=\{100 ; 150 ; 200\}$ and $W=\{897 ; 847 ; 797\})$. Sets for the larger instances were chosen in a similar way: again, the size of $T$ was set to 3,5 and 10 and $W=(V \subset W)-(T+V)$, but now the size of $V$ was $0.06,0.08$ and 0.1 times $V \subset W=\{2000\}$ (e.g.: for $T=\{3\}, 3$ instances were run with $V=\{120 ; 160 ; 200\}$ and $W=\{1877 ; 1837 ; 1797\}) .9$ different types of each problem were created.

In my first approach, the covering distance $c$ was set to the minimum distance at which the CTP is still feasible. I applied CTACS and H-1-CTP to the problems. The tables below outline the results.

As in previous tables, the cost of a tour written in bold letters represents the best obtained solution for an instance. In all CTP tables, column "Problem" specifies the test instance, "Cover distance" gives the used constant cover distance $c$, "Tour size" shows the number of tour stops and "Time" the runtime of the individual algorithm. The column "Gap (\%)" refers to the difference in percentage between CTACS and H -1-CTP where a negative number implies that CTACS provides a better solution. Finally, "Total runtime" refers to the time allowed for both algorithms on an instance. This is the time needed by CTACS to run through the problem. The number of iterations for the SCACS part of CTACS equalled the size of $V$ while GACS iterations equalled the number of columns produced by SCACS (which refers to the CTACS tour size column in the tables).

| Problem | Cover distance | CTACS |  |  | H-1-CTP |  |  | Gap | Total Runtime |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

Table 17: Results for CTACS and H-1-CTP with $V \subset W=\{2000\}$

The tests confirm that CTACS dominates $\mathrm{H}-1$-CTP in the majority of the problems. The main reason is the far better performance of SCACS compared to PRIMAL1. The importance of the tour construction components GACS and GENIUS in these smaller problems seems to be rather low but, as I have demonstrated earlier (4.1.3), CTACS would also outperform H-1-CTP with larger tour sizes. However, H-1-CTP finds its best solutions faster than CTACS. In addition, the results show an obvious inverse relationship between cover distance and tour length. Although the minimum distance choice allows a good comparison of the two algorithms, it is not very helpful for comparing the effects of different sizes of $T$ and $V$ (inter-problem comparison).

Therefore I set the covering distance $c$ to 20 for all problems and variants in order to focus on inter-problem comparison and ran both algorithms a second time (tables 18 and 19).

| Problem | Cover distance | CTACS |  |  | H-1-CTP |  |  | Gap | Total Runtime |

Table 19: Results for CTACS and H-1-CTP with $V \subset W=\{2000\}$ and $c=20$

Again, CTACS dominates H-1-CTP but the interesting finding when dealing with a constant covering distance was that a greater pool of possible tour stops can lead to better solutions, even if more stops are made. On the other hand the solution quality may suffer if vertices of set $T$ that would not have been chosen had they been members of set $V$, increase the length of the tour.

## 5 Conclusion

The CTP is an important problem with highly relevant issues in the public and private sector. It is an NP-hard combinatorial optimization problem. The objective is to determine a minimum length tour over a subset of vertices while covering another set of vertices. Good examples for CTP applications are the design of bi-level transportation networks or the deployment of a mobile medical facility in developing countries.
This thesis shows two methods for solving the CTP. I divided the problem into two other optimization problems, namely the TSP and the SCP, both also NPhard problems. The objective of the TSP is to construct the shortest tour over a set of vertices and return to the starting point while in the SCP a set of columns that covers a set of rows at minimum cost has to be determined. I combined solution approaches for them in order to solve the CTP. I created the following algorithms with C++ programming language:
The first approach, an approximation algorithm called H-1-CTP created by Gendreau et al. [14], delivers good solutions but seems to get caught in local optima as it only considers the best insertions. Nevertheless, especially the GENIUS heuristic, responsible for constructing the TSP tour, leads to better solutions than other heuristics due to a random choice of the next vertex to be inserted.

I created the second approach called CTACS, a combination of two ACS algorithms for the TSP and the SCP, myself. This method outperforms the first one in over 82 percent of the instances because it also allows inferior steps during construction with a certain amount of probability.
The main barrier of evaluating the solution quality of both algorithms was that no model problems exist for comparison. Consequently, I first tested the individual methods used to solve the TSP (namely GENI, GENIUS and GACS) and the SCP (namely PRIMAL1 and SCACS) and compared them to the best known solutions obtained from the TSPLIB [24] and ORLIB [4]. All solution methods using ACS and GENI as well as US returned very good results so I assume that, at least for CTACS, the solution quality, when dealing with CTPs, will be able to bear comparison with other approaches to come.

However, the time needed to generate solutions for the CTP must be seen critically and can surely be improved with more C++ experience. In addition,
the introduction of local search especially to SCACS should improve solution quality a bit more, leading to optimal results.

## Appendix A

Appendix A shows detailed GACS results for every one of the four problems analyzed (KubLE25, Berlin52, st70 and pr107). Four tables for each problem for parameters $q_{0}, \gamma, \alpha$ and $\rho$ with the results for ten runs on each parameter setting follow. The values which are lower or equal to the best average cost of each parameter are written in bold letters.

## KubLE25:

Table 35: Tests on $\rho$ for pr107 (GACS)

## Appendix B

Appendix B lists SCACS results for the four problems analyzed (SCP41, SCP43, SCP44, SCP57). Four tables for each problem for parameters $q_{0}, \gamma, \alpha$ and $\rho$ with the results of ten runs on each parameter setting follow. The values lower or equal to the best average cost of each parameter are written in bold letters.

## SCP41:

| SCP41 Parameter $\boldsymbol{\alpha}$ |  |  |  |
| :---: | :---: | :---: | :---: |
| Runs | $\mathbf{0 . 1}$ | $\mathbf{0 . 2}$ | $\mathbf{0 . 3}$ |
| $\mathbf{1}$ | 585 | 537 | $\mathbf{4 6 7}$ |
| $\mathbf{2}$ | 520 | 512 | 577 |
| $\mathbf{3}$ | 541 | $\mathbf{5 0 3}$ | 586 |
| $\mathbf{4}$ | 689 | $\mathbf{4 7 7}$ | 516 |
| $\mathbf{5}$ | 528 | $\mathbf{4 8 1}$ | 537 |
| $\mathbf{6}$ | 508 | $\mathbf{4 8 7}$ | $\mathbf{5 0 0}$ |
| $\mathbf{7}$ | 539 | 507 | 598 |
| $\mathbf{8}$ | $\mathbf{4 9 0}$ | 536 | 531 |
| $\mathbf{9}$ | 706 | $\mathbf{4 6 4}$ | 554 |
| $\mathbf{1 0}$ | 603 | 538 | $\mathbf{4 7 4}$ |
| Average | 570.9 | $\mathbf{5 0 4 . 2}$ | 534 |
| Minimum | 490 | 464 | 467 |
| Maximum | 706 | 538 | 598 |

Table 36: Tests on $\alpha$ for SCP41 (SCACS)

| SCP41 Parameter $\beta$ |  |  |  |
| :---: | :---: | :---: | :---: |
| Runs | $\mathbf{1}$ | $\mathbf{3}$ | $\mathbf{5}$ |

## Appendix C

## C. 1 German Abstract

Diese Arbeit beschäftigt sich mit dem Covering Tour Problem (CTP) und verschiedenen heuristischen Lösungsmethoden. Dieses Problem der Tourenplanung zählt zu den kombinatorischen Optimierungsproblemen, welche sehr oft im Bereich der Distributionslogistik international agierender Großunternehmen auftreten und durch deren Lösung man entsprechend Kosten einsparen und Gewinne maximieren kann. Im Zuge der Globalisierung der Weltwirtschaft rückt das Problem der Distributionskosten immer mehr in den Mittelpunkt.

Das CTP kann auf einem ungerichteten Graphen $G=(V \cup W, E)$ definiert werden. $V \cup W$ ist eine Menge von Knoten. $V=\left\{v_{0}, \ldots ., v_{n}\right\}$ sind jene Knoten, die von der zu konstruierenden Tour besucht werden können. $T \subset V$ ist eine Teilmenge von $V$ und beinhaltet jene Knoten, die von der Tour besucht werden müssen. $W$ ist die Menge jener Knoten, welche von der Tour abgedeckt werden müssen, also in einer vorgegebenen Entfernung zur Tour liegen müssen. Das Kantenset $E=\left\{\left(v_{i}, v_{j}\right): v_{i}, v_{j} \in V \cup W, i<j\right\}$ beinhaltet die Verbindungen zwischen sämtlichen Knoten. Ziel ist es nun, eine möglichst kurze Tour zu finden, die im Punkt $v_{0}$ beginnt, alle Knoten aus $T \subset V$ besucht, sämtliche Knoten aus $W$ abdeckt und wieder in $v_{0}$ endet.

Um das Problem zu lösen, wurde das CTP gemäß einer bereits angewandten Methode[14] in zwei Subprobleme, nämlich das Traveling Salesman Problem (TSP) und das Set Covering Problem (SCP) unterteilt und diese wurden vorgestellt. Nach einer kurzen Einführung der Ant Colony Optimierung wurden die Algorithmen GENI, GENIUS und GENI Ant Colony System für den TSP Teil und PRIMAL1 sowie ein Set Covering Ant Colony System für den SCP Teil detailliert beschrieben. In weitere Folge wurde erklärt, wie man die Algorithmen kombinieren kann, um das CTP zu lösen.
Sämtliche Algorithmen wurden mit Hilfe der Programmiersprache C++ simuliert und getestet. Zunächst wurden die Algorithmen an Instanzen einer Datenbank getestet und mit bereits vorhandenen Lösungen verglichen, um ihre Funktionalität und Konkurrenzfähigkeit zu überprüfen. Da für das CTP keine

Vergleichsinstanzen vorhanden sind, wurden stochastische Probleme entworfen und mit dem H -1-CTP Algorithmus [14] und der von mir entworfenen Metaheuristik Covering Tour Ant Colony System bestehend aus GENI Ant Colony System und Set Covering Ant Colony System gelöst und die Ergebnisse verglichen, um dann die beiden Lösungsansätze zu bewerten.

## C. 2 English Abstract

This thesis deals with the Covering Tour Problem (CTP) and different heuristic solution approaches. It can be classified as a combinatorial optimization problem. Logistics and distribution departments of economic global players have to handle this sort of problems to reduce costs and maximize profit. Distribution costs enjoy increasing importance due to the globalization of world economy.

The CTP is defined on a complete undirected graph $G=(V \cup W, E)$ with a set of vertices $V \cup W$ where $V=\left\{v_{0}, \ldots ., v_{n}\right\}$ is a set of vertices that can be visited, $W$ defines the set of vertices that have to be covered by the tour and $E=\left\{\left(v_{i}, v_{j}\right): v_{i}, v_{j} \in V \cup W, i<j\right\}$ is the set of edges. "Covered by the tour" means that any vertex $v_{\ell} \in W$ has to lie within a predefined distance of a vertex on the tour. The set $V$ includes the subset $T$ which includes the vertices that have to be visited by the tour. The solution to the CTP is a minimum length tour. The tour starts and ends at the depot and is defined by a certain subset so that all vertices that have to be visited are visited by the tour and all vertices that have to be covered lie within a predetermined distance of a vertex belonging to the tour.

In order to solve the problem, it was classified as a combination of the Traveling Salesman Problem (TSP) and the Set Covering Problem (SCP) and the components were introduced. After a short description of Ant Colony Optimization, algorithms GENI, GENIUS and GENI Ant Colony System for the TSP part and PRIMAL1 as well as Set Covering Ant Colony System for the SCP part were introduced in detail. Then the combinations of these algorithms for solving the CTP were described.
All algorithms were simulated and tested with the help of C++ programming language. First, algorithms were tested individually on instances from data libraries to ensure their functionality and competitiveness. Then stochastic instances were developed for the CTP because no comparable benchmarks exist and the $\mathrm{H}-1-\mathrm{CTP}$ algorithm as well as the Covering Tour Ant Colony System, that I created myself, were run on these instances and results were compared.

## C. 3 Curriculum vitae

## Personal Details

| Name: | Patrick Kubik |
| :--- | :--- |
| Date of Birth: | 7 January 1981 |
| Nationality: | Austrian |
| Marital Status: | Single |

## Education

University: International Business Management at the University of Vienna (masters degree)

October 2000 - December 2007
Fields of specialization: operations management, corporate finance and transportation logistics

High School: Bundesgymnasium Stockerau (1991-1999)
Matura (equivalent of A-Level) passed with distinction (grade average 2)

## Professional Experience

## Since Sept 2005 CUBE Consult Unternehmensberatungs Gmbh <br> Junior Analyst

July - Aug 2004 Boehler Uddeholm GmbH Germany, Duesseldorf<br>Internship in the accounting department (participation in preparing the quarterly statement and in creating forecasts, corporate group reporting with SAP and Hyperion, cost centre planning) and the sales department (sales management and budget planning)

July 2003 VA Tech Finance GmbH \& Co, Vienna
Internship assisting the managing director in writing a paper ("Anticipating Credit Risks") for a textbook for Austrian Universities

July 2001,2002 Boehler Uddeholm AG, Vienna
Internship in the treasury department (participation in hedging activity, cash pooling and credit insurance management)

## Language Skills

German (native language)
English (bilingual/excellent - mother comes from England)
French (basic knowledge - second foreign language at university)

## Computer Skills

Microsoft Office (Word, Excel, Power Point) experienced
Programming (Pascal, Java) basic knowledge, (C++) advanced
Arena (simulation software) advanced
SAP basic knowledge

## Further activities

Handball (since 1988, semi-professional from 1999 until 2002/Club: UHC Stockerau)

Catholic youth group (organising charity work and weekly events, leader of a group of 14-16 year olds with weekly meetings including discussions and creative activities, organisation of the cocktail bar at the yearly ball, organisation of other activities like football tournaments or Christmas parties)
